

Package ‘Umpire’

July 21, 2025

Version 2.0.11

Date 2025-02-04

Title Simulating Realistic Gene Expression and Clinical Data

Description The Ultimate Microarray Prediction, Reality and Inference Engine (UMPIRE) is a package to facilitate the simulation of realistic microarray data sets with links to associated outcomes. See Zhang and Coombes (2012) <[doi:10.1186/1471-2105-13-S13-S1](https://doi.org/10.1186/1471-2105-13-S13-S1)>. Version 2.0 adds the ability to simulate realistic mixed-typed clinical data.

Depends R (>= 3.0)

Imports methods, stats, mc2d, BimodalIndex

Suggests mclust, survival, knitr, rmarkdown

License Apache License (== 2.0)

addControl-method	<i>Method "addControl"</i>
-------------------	----------------------------

Description

addControl is a generic function used to add a control group to a simulated patient cohort. Implementations exists for a CancerModel and for a CancerEngine.

Usage

```
## S4 method for signature 'ANY'
addControl(object, fraction = 0.5, ...)
## S4 method for signature 'CancerModel'
addControl(object, fraction = 0.5, ...)
## S4 method for signature 'CancerEngine'
addControl(object, fraction = 0.5, ...)
```

Arguments

object	an object to which adding a control group is desired
fraction	a real number between zero and one; the fraction of the final cohort that should consist of controls
...	additional arguments; not yet used

Value

Returns a new object of the same class as its first argument.

Author(s)

Kevin R. Coombes <krc@silicovore.com>,

alterMean-method *Methods "alterMean" and "alterSD"*

Description

alterMean and alterSD are generic functions used to alter means or standard deviations, respectively, based on the input object. Each generic functions invokes different [methods](#) which depend on the [class](#) of the first argument.

Usage

```
## S4 method for signature 'ANY'
alterMean(object, TRANSFORM, ...)
## S4 method for signature 'ANY'
alterSD(object, TRANSFORM, ...)
```

Arguments

object	an object for which altering mean or standard deviation is desired
TRANSFORM	function that returns its transformed input
...	additional arguments affecting the specific transformation performed

Value

The form of the value returned by alterMean or alterSD depends on the class of its argument. See the documentation of the particular methods for details of what is produced by that method.

BlockHyperParameters-class

The "BlockHyperParameters" Class

Description

Provides tools to create a CancerEngine with block correlation structure. Also makes it possible to simulate paired clinical and gene expression data with this block structure.

Usage

```
BlockHyperParameters(nExtraBlocks = 100,
                     meanBlockSize = 100,
                     sigmaBlockSize = 30,
                     minBlockSize = 5,
                     mu0 = 6,
                     sigma0 = 1.5,
                     rate = 28.11,
                     shape = 44.25,
                     p.cor = 0.6,
                     wt.cor = 5)
makeBlockStructure(cm, hyperp, xform = normalOffset, ...)
```

Arguments

<code>cm</code>	object of class <code>CancerModel</code>
<code>hyperp</code>	object of class <code>BlockHyperParameters</code>
<code>nExtraBlocks</code>	integer scalar specifying number of blocks not involved in the "hit" structure defined by the <code>CancerModel</code>
<code>meanBlockSize</code>	numeric scalar specifying mean number of genes in a correlated block
<code>sigmaBlockSize</code>	numeric scalar specifying standard deviation of the number of genes in a correlated block
<code>minBlockSize</code>	integer scalar specifying minimal number of genes in a correlated block
<code>mu0</code>	numeric scalar specifying expected mean expression level of a gene on the log scale
<code>sigma0</code>	numeric scalar specifying standard deviation of the mean expression level of a gene on the log scale
<code>rate</code>	numeric scalar specifying one of the gamma parameters
<code>shape</code>	numeric scalar specifying one of the gamma parameters
<code>p.cor</code>	numeric scalar specifying expected correlation within each block
<code>wt.cor</code>	numeric scalar specifying weight given to the expected block correlation
<code>xform</code>	A function that will be passed to the <code>alterMean</code> method
<code>...</code>	extra arguments that will be passed back to the <code>xform</code> function

Details

Our standard model for gene expression in a homogeneous sample assumes that the overall correlation matrix is block diagonal. Correlation between genes in different blocks is assumed to be zero. Correlation for genes in the same block is assumed to be a constant, but different correlation constants can be used in different blocks. The actual correlations are assumed to arise from a beta distribution of the form $\text{Beta}(pw, (1-p)w)$, where $p=p.cor$ and $w=wt.cor$ are two of the hyperparameters.

The number of blocks is determined jointly by the `CancerModel`, `cm`, and the hyperparameter `nExtraBlocks`. The size of a block is assumed to arise from a normal distribution with mean

given by `meanBlockSize` and standard deviation given by `sigmaBlockSize`. To avoid accidentally assigning non-positive block sizes, this distribution is truncated below by `minBlockSize`.

The expression of each gene is assumed to come from a log-normal distribution with parameters describing the per-gene mean (μ_g) and standard deviation (σ_g) on the log scale. These parameters, in turn, are assumed to come from hyperdistributions. Specifically, we assume that μ_g comes from a normal distribution with mean `mu0` and standard deviation `sigma0`. We also assume that σ_g comes from an inverse gamma distribution with parameters `rate` and `shape`.

The `BlockHyperParameters` class simply bundles the parameters for this model into a single structure. The default values are consistent with data we have seen from several Affymetrix microarray studies.

The `makeBlockStructure` function takes a `CancerModel` and a `BlockHyperParameters` object as arguments and produces a `CancerEngine` object. The `rand` method for this class can be used to generate matched clinical data (with the structure defined by the `CancerModel` object) and gene expression data with the specified block correlation structure.

Value

The `BlockHyperParameters` generator returns an object of class `BlockHyperParameters`.

The function `makeBlockStructure` returns an object of the `CancerEngine` class.

Objects from the Class

Although objects of the class can be created by a direct call to `new`, the preferred method is to use the `BlockHyperParameters` generator function.

Slots

`nExtraBlocks`: An integer; the number of blocks not involved in the "hit" structure defined by the `CancerModel`.

`meanBlockSize`: A real number; the mean number of genes in a correlated block.

`sigmaBlockSize`: A real number; standard deviation of the number of genes in a correlated block.

`minBlockSize`: An integer; the minimal number of genes in a correlated block.

`mu0`: A real number; the expected mean expression level of a gene on the log scale.

`sigma0`: A real number; the standard deviation of the mean expression level of a gene on the log scale.

`rate`: Gamma parameter; see details.

`shape`: Gamma parameter; see details.

`p.cor`: A real number; the expected correlation within each block.

`wt.cor`: A real number; the weight given to the expected block correlation.

Methods

There are no special methods defined for this class.

Examples

```
showClass("BlockHyperParameters")
sm <- SurvivalModel(baseHazard = 1/3, units = 52, unitName = "weeks")
cm <- CancerModel("myModel", nPossible = 10, nPattern = 5,
                 survivalModel = sm)
hyper <- BlockHyperParameters()
engine <- makeBlockStructure(cm, hyper)
outcome <- rand(engine, 100)
summary(outcome$clinical)
dim(outcome$data)
```

blur-method

Method "blur"

Description

blur is a generic function used to add noise to a signal as defined by various objects. The generic function invokes different [methods](#) which depend on the [class](#) of the first argument.

Usage

```
## S4 method for signature 'ANY'
blur(object, x, ...)
```

Arguments

object	an object from which adding noise to its signal is desired
x	matrix containing signal to be affected
...	additional arguments affecting the noise addition

Value

The form of the value returned by blur depends on the class of its argument. See the documentation of the particular methods for details of what is produced by that method.

 CancerEngine-class *The "CancerEngine" Class*

Description

A CancerEngine combines a CancerModel (which defines the combinatorics of hits that produce cancer subtypes) with a pair of gene expression Engines that can be used to simulate microarray data depending on the presence or absence of different hits.

Usage

```
CancerEngine(cm, base, altered)
## S4 method for signature 'CancerEngine'
summary(object, ...)
## S4 method for signature 'CancerEngine'
nrow(x)
## S4 method for signature 'CancerEngine'
nComponents(object, ...)
## S4 method for signature 'CancerEngine'
rand(object, n, ...)
ClinicalEngine(nFeatures, nClusters, isWeighted,
               bHyp = NULL, survivalModel = NULL,
               SURV = function(n) rnorm(n, 0, 0.3),
               OUT = function(n) rnorm(n, 0, 0.3))
```

Arguments

cm	object of class CancerModel
base	character string giving the name of an Engine or EngineWithActivity , or an object of class Engine. Represents the expected gene expression in the absence of any hits.
altered	character string giving the name of an Engine or EngineWithActivity , or an object of class Engine. Represents the expected gene expression in the presence of hits.
object	object of class CancerEngine
x	object of class CancerEngine
n	numeric scalar representing number of samples to be simulated
...	extra arguments for generic routines
nFeatures	an integer; the number of simulated clinical features
nClusters	an integer; the number of simulated clusters or subtypes
isWeighted	a logical value; used to determine whether the prevalence of subtypes is equal (unweighted) or unequal (weighted).
bHyp	an object of the class BlockHyperParameters. If NULL, then it is constructed using the default clinical parameters. See the Values section below.

survivalModel	an object of the SurvivalModel class. If NULL, then it is constructed using the default parameters.
SURV	a function; the same as used in a CancerModel .
OUT	a function; the same as used in a CancerModel .

Objects from the Class

Although objects of the class can be created by a direct call to `new`, the preferred method is to use the `CancerEngine` or `ClinicalEngine` generator functions.

Slots

- `cm`: A [CancerModel](#) object.
- `base`: Object of class "character" giving the name of an [Engine](#) or [EngineWithActivity](#). Represents the expected gene expression in the absence of any hits.
- `altered`: Object of class "character" giving the name of an [Engine](#) or [EngineWithActivity](#). Represents the expected gene expression in the presence of hits.
- `localenv`: Object of class "environment"; used in the internal implementation.

Methods

- rand** signature(object = "CancerEngine"): returns a list containing two named components, `clinical` and `data`. The `clinical` element is a data frame generated from the underlying [CancerModel](#), and the `data` element is a matrix generated by the gene expression engines, altered by the appropriate "hits" present in each simulated individual.
- summary** signature(object = "CancerEngine"): print summaries of the underlying cancer models and gene expression engines in the cancer engine.

Values

Both the `CancerEngine` and `ClinicalEngine` constructors return objects of the `CancerEngine` class. The only practical differences are the default parameters set by the constructors. The primary change is in the [CancerModel](#) slot. The `CancerEngine` expects you to construct your own [CancerModel](#) explicitly before producing a `CancerEngine`.

By contrast, the `ClinicalEngine` expects to use many fewer features, so gives a simpler interface and uses its parameters to construct the [CancerModel](#) for you. The "HIT" function will use 2 hits per subtype when there are fewer than 15 features, 3 hits between 15 and 45 features, and the older default of 5 hits when there are more than 45 features. The total number of possible hits is set equal to the number of features (N) when there are fewer than 12 features, approximately N/3 up to 50 features, approximately N/5 up to 100, and is then locked at 20. If `isWeighted` is TRUE, subtype prevalences are chosen from a Dirichlet distribution. Otherwise, each subtype is equally likely.

The `nrow` and `nComponents` methods both return non-negative integer values describing the number of rows (features) and the number of components of the underlying gene expression or clinical data Engines. The `rand` method returns a matrix with `n` columns of simulated data.

CancerModel-class *The "CancerModel" Class*

Description

A CancerModel object contains a number of pieces of information representing an abstract, heterogeneous collection of cancer patients. It can be used to simulate patient outcome data linked to hit classes.

Usage

```

CancerModel(name,
             nPossible,
             nPattern,
             HIT = function(n) 5,
             SURV = function(n) rnorm(n, 0, 0.3),
             OUT = function(n) rnorm(n, 0, 0.3),
             survivalModel=NULL,
             prevalence=NULL)
nPatterns(object)
nPossibleHits(object)
nHitsPerPattern(object)
outcomeCoefficients(object)
survivalCoefficients(object)
## S4 method for signature 'CancerModel'
ncol(x)
## S4 method for signature 'CancerModel'
nrow(x)
## S4 method for signature 'CancerModel'
rand(object, n, balance = FALSE, ...)
## S4 method for signature 'CancerModel'
summary(object, ...)

```

Arguments

name character string specifying name given to this model

object, x	object of class CancerModel
nPossible	integer scalar specifying number of potential hits relevant to the kind of cancer being modeled
nPattern	integer scalar specifying number of different cancer subtypes
HIT	function that generates non-negative integers from a discrete distribution. Used to determine the number of hits actually present in each cancer subtype.
SURV	function that generates real numbers from a continuous distributions. Used in simulations to select the coefficients associated with each hit in Cox proportional hazards models.
OUT	function that generates real numbers from a continuous distributions. Used in simulations to select the coefficients associated with each hit in logistic models of a binary outcome.
survivalModel	object of class SurvivalModel used to simulate survival times for each simulated patient
prevalence	optional numeric vector of relative prevalences of cancer subtypes
n	numeric scalar specifying quantity of random numbers
balance	logical scalar specifying how patients should be simulated
...	extra arguments for generic routines

Details

The `rand` method is the most important method for objects of this class. It returns a data frame with four columns: the `CancerSubType` (as an integer that indexes into the `hitPattern` slot of the object), a binary `Outcome` that takes on values "Bad" or "Good", an `LFU` column with censored survival times, and a logical `Event` column that describes whether the simulated survival event has occurred.

The `rand` method for the `CancerModel` class adds an extra logical parameter, `balance`, to the signature specified by the default method. If `balance = FALSE` (the default), then patients are simulated based on the prevalence defined as part of the model. If `balance = TRUE`, then patients are simulated with equal numbers in each hit pattern class, ordered by the hit pattern class.

Value

The `CancerModel` function is used to construct and return an object of the `CancerModel` class.

The `ncol` and `nrow` functions return integers with the size of the matrix of hit patterns.

The `rand` method returns data frame with four columns:

<code>CancerSubType</code>	integer index into object's 'hitPattern' slot
<code>Outcome</code>	outcomes with values "Bad" or "Good"
<code>LFU</code>	censored survival times
<code>Event</code>	has simulated survival event has occurred?

Objects from the Class

Although objects of the class can be created by a direct call to `new`, the preferred method is to use the `CancerModel` generator function.

Slots

name: Object of class "character"
hitPattern: Object of class "matrix"
survivalBeta: Object of class "numeric" containing the coefficients associated with each hit in a Cox proportional hazards model of survival.
outcomeBeta: Object of class "numeric" containing the coefficients associated with each hit in a logistic model to predict a binary outcome.
prevalence: Object of class "numeric" containing the prevalence of each cancer subtype.
survivalModel: Object of class "survivalModel" containing parameters used to simulate survival times.
call: object of class "call" recording the function call used to initialize the object.

Methods

ncol signature(x = "CancerModel"): ...
nrow signature(x = "CancerModel"): ...
rand signature(object = "CancerModel"): ...
summary signature(object = "CancerModel"): ...

```

ClinicalNoiseModel *A Noise Model for Clinical Data*

Description

A ClinicalNoiseModel represents the additional human and measurement noise that is layered on top of any biological variability when measuring clinical variables.

Usage

```
ClinicalNoiseModel(nFeatures, shape = 1.02, scale = 0.05/shape)
```

Arguments

nFeatures	An integer; the number of additive scale parameters to sample from the gamma distribution.
shape	The shape gamma hyperparameter describing the standard deviation of additive noise.
scale	The scale gamma hyperparameter describing the standard deviation of additive noise.

Details

We model both additive and multiplicative noise, so that the observed expression of clinical variable c in sample i is given by: $Y_{ci} = S_{ci} + E_{ci}$, where Y_{ci} = observed expression, S_{ci} = true biological signal. In the ClinicalNoiseModel (as opposed to the [NoiseModel](#)), we model the additive noise as $E_{ci} \sim N(0, \tau)$, without multiplicative noise or an additive bias/offset in the clinical model. The standard deviation hyperparameters of the additive noise τ is modeled by the gamma distribution $\tau \sim \text{Gamma}(\text{shape}, \text{scale})$

Value

An object of class [NoiseModel](#).

```

Engine-class

The "Engine" Class

Description

The Engine class is a tool (i.e., an algorithm) used to simulate vectors of gene expression from some underlying distribution.

Usage

```

Engine(components)
## S4 method for signature 'Engine'
nComponents(object, ...)
## S4 method for signature 'Engine'
alterMean(object, TRANSFORM, ...)
## S4 method for signature 'Engine'
alterSD(object, TRANSFORM, ...)
## S4 method for signature 'Engine'
nrow(x)
## S4 method for signature 'Engine'
rand(object, n, ...)
## S4 method for signature 'Engine'
summary(object, ...)

```

Arguments

components	object of class list, each element of which contains the parameters for the underlying distribution that the gene expression follows. A component can be viewed as a special case of an engine that only has one component.
object, x	object of class Engine
TRANSFORM	function takes as its input a vector of mean expression or standard deviation and returns a transformed vector that can be used to alter the appropriate slot of the object.

n numeric scalar representing number of samples to be simulated
 . . . extra arguments for generic or plotting routines

Details

In most cases, an engine object is an instantiation of a more general family or class that we call an ABSTRACT ENGINE. Every abstract engine is an ordered list of components, which can also be thought of as an engine with parameters. We instantiate an engine by binding all the free parameters of an abstract engine to actual values. Note that partial binding (of a subset of the free parameters) produces another abstract engine.

For all practical purposes, a COMPONENT should be viewed as an irreducible abstract engine. Every component must have an IDENTIFIER that is unique within the context of its enclosing abstract engine. The identifier may be implicitly taken to be the position of the component in the ordered list.

We interpret an Engine as the gene expression generator for a homogenous population; effects of cancer on gene expression are modeled at a higher level.

Value

The Engine generator returns an object of class Engine.

The alterMean method returns an object of class Engine with altered mean.

The alterSD method returns an object of class Engine with altered standard deviation.

The nrow method returns the number of genes (i.e, the length of the vector) the Engine object will generate.

The rand method returns $nrow(Engine) * n$ matrix representing the expressions of $nrow(Engine)$ genes and n samples.

The summary method prints out the number of components included in the Engine object.

The nComponents method returns the number of components in the Engine object.

Objects from the Class

Objects can be created by calls of the form `new("Engine", components=components)`, or use the Engine generator function. Every engine is an ordered list of components, which generates a contiguous subvector of the total vector of gene expression.

Methods

alterMean(object, TRANSFORM, ...) Takes an object of class Engine, loops over the components in the Engine, alters the mean as defined by TRANSFORM function, and returns a modified object of class Engine.

alterSD(object, TRANSFORM, ...) Takes an object of class Engine, loops over the components in the Engine, alters the standard deviation as defined by TRANSFORM function, and returns a modified object of class Engine.

nrow(x) Counts the total number of genes (i.e, the length of the vector the Engine will generate).

rand(object, n, ...) Generates $nrow(Engine) * n$ matrix representing gene expressions of n samples following the underlying distribution captured in the object of Engine.

summary(object, ...) Prints out the number of components included in the object of Engine.

EngineWithActivity-class

The "EngineWithActivity" Class

Description

The EngineWithActivity is used to set some components in the object of class Engine to be transcriptionally inactive and transform the expression data to appropriate logarithmic scale.

Usage

```

EngineWithActivity(active, components, base=2)
## S4 method for signature 'EngineWithActivity'
rand(object, n, ...)
## S4 method for signature 'EngineWithActivity'
summary(object, ...)

```

Arguments

active	logical vector with length equal to number of components specifying whether each component should be transcriptionally active, or a numeric scalar specifying the probability for a component to be active
components	list where each element contains the parameters for the underlying distribution that the gene expression follows
base	numeric scalar specifying the logarithmic scale to which the data should be transformed
object	object of class EngineWithActivity
n	number of samples to be simulated
...	extra arguments for generic routines

Details

An ENGINE WITH ACTIVITY allows for the possibility that some components (or genes) in an expression engine (or tissue) might be transcriptionally inactive. Thus, the true biological signal S_{gi} should really be viewed as a mixture:

$$S_{gi} = z_g * \text{delta}_0 + (1 - z_g) * T_{gi}$$

where delta_0 = a point mass at zero; T_{gi} = a random variable supported on the positive real line; $z_g \sim \text{Binom}(\pi)$ defines the activity state (1 = on, 0 = off)

The rand method for an EngineWithActivity is a little bit tricky, since we do two things at once. First, we use the base slot to exponentiate the random variables generated by the underlying Engine on the log scale. We treat $\text{base} = 0$ as a special case, which means that we should continue to work on the scale of the Engine. Second, we mask any inactive component by replacing the generated values with 0.

Note that this is terribly inefficient if we only have a single homogeneous population, since we generate a certain amount of data only to throw it away. The power comes when we allow cancer dysregulation to turn a block on or off, when the underlying data reappears.

Value

The EngineWithActivity generator returns an object of class EngineWithActivity.

The rand method returns $nrow(\text{EngineWithActivity}) * n$ gene expression matrix with the inactive components being masked by 0.

The summary method prints out the total number of components and the number of active components in the object of EngineWithActivity.

Objects from the Class

Although objects of the class can be created by a direct call to `new`, the preferred method is to use the `EngineWithActivity` generator function.

Slots

`active`: logical vector specifying whether each component should be transcriptionally active or not

`base`: numeric scalar specifying the logarithmic scale

`components`: list specifying the parameters of the underlying distribution

Extends

Class `Engine`, directly.

Methods

rand(object, n, ...) Generates `nrow(EngineWithActivity)*n` matrix representing gene expressions of `n` samples, and the transcriptionally inactive components are masked by `0`.

summary(object, ...) Prints out the total number of components and the number of active components in the object of `EngineWithActivity`.

Author(s)

Kevin R. Coombes <krc@silicovore.com>, Jiexin Zhang <jiexinzhang@mdanderson.org>,

Examples

```
showClass("EngineWithActivity")
nComponents <- 10
nGenes <- 100
active <- 0.7
comp <- list()
for (i in 1:nComponents) {
  comp[[i]] <- IndependentNormal(rnorm(nGenes/nComponents, 6, 1.5),
                                1/rgamma(nGenes/nComponents, 44, 28))
}
myEngine <- EngineWithActivity(active, comp, 2)
summary(myEngine)
myData <- rand(myEngine, 5)
dim(myData)
```

 IndependentLogNormal-class

The "IndependentLogNormal" Class

Description

The IndependentLogNormal class is a tool used to generate gene expressions that follow log normal distribution, because the true expression value follows log normal in our model.

Usage

```

IndependentLogNormal(logmu, logsigma)
## S4 method for signature 'IndependentLogNormal'
alterMean(object, TRANSFORM, ...)
## S4 method for signature 'IndependentLogNormal'
alterSD(object, TRANSFORM, ...)
## S4 method for signature 'IndependentLogNormal'
nrow(x)
## S4 method for signature 'IndependentLogNormal'
rand(object, n, ...)
## S4 method for signature 'IndependentLogNormal'
summary(object, ...)

```

Arguments

logmu	numeric vector specifying the mean expression values on the logarithmic scale.
logsigma	numeric vector specifying the standard deviation of the gene expression values on the logarithmic scale
object, x	object of class IndependentLogNormal
TRANSFORM	function that takes a vector of mean expression or standard deviation and returns a transformed vector that can be used to alter the appropriate slot of the object.
n	numeric scalar specifying number of samples to be simulated
...	extra arguments for generic or plotting routines

Objects from the Class

Although objects of the class can be created by a direct call to `new`, the preferred method is to use the IndependentLogNormal generator function.

Slots

logmu: numeric vector containing the mean expression values on the logarithmic scale

logsigma: numeric vector containing the standard deviation of the gene expression values on the logarithmic scale

Methods

nrow(x) Returns the number of genes (i.e, the length of the logmu vector).

rand(object, n, ...) Generates $nrow(\text{IndependentLogNormal}) * n$ matrix representing gene expressions of n samples following log normal distribution captured in the object of IndependentLogNormal.

summary(object, ...) Prints out the number of independent log normal random variables in the object of IndependentLogNormal.

ln <- IndependentLogNormal(logmu, logsigma)
nrow(ln)
summary(ln)
if (any(logmu - ln@logmu)) {
  print('means do not match')
} else {
  print('means verified')
}
if (any(logsigma - ln@logsigma)) {
  print('standard deviations do not match')
} else {
  print('sd verified')
}
x <- rand(ln, 1000)
print(dim(x))

print(paste("'ln' should be valid:", validObject(ln)))
ln@logsigma <- 1:3 # now we break it
print(paste("'ln' should not be valid:", validObject(ln, test=TRUE)))
tmp.sd <- sqrt(apply(log(x), 1, var))
plot(tmp.sd, logsigma)
tmp.mu <- apply(log(x), 1, mean)
plot(tmp.mu, logmu)
rm(nGenes, logmu, logsigma, ln, x, tmp.mu, tmp.sd)
```

IndependentNormal-class

The "IndependentNormal" Class

Description

The IndependentNormal class is a tool used to generate gene expressions that follow independent normal distribution.

Usage

```
IndependentNormal(mu, sigma)
## S4 method for signature 'IndependentNormal'
alterMean(object, TRANSFORM, ...)
## S4 method for signature 'IndependentNormal'
alterSD(object, TRANSFORM, ...)
## S4 method for signature 'IndependentNormal'
nrow(x)
## S4 method for signature 'IndependentNormal'
rand(object, n, ...)
## S4 method for signature 'IndependentNormal'
summary(object, ...)
```

Arguments

mu	numeric vector specifying the mean expression values
sigma	numeric vector specifying the standard deviation of the gene expression values
object, x	object of class IndependentNormal
TRANSFORM	function that takes a vector of mean expression or standard deviation and returns a transformed vector that can be used to alter the appropriate slot of the object.
n	numeric scalar specifying number of samples to be simulated
...	extra arguments for generic or plotting routines

Details

Note that we typically work on expression value with its logarithm to some appropriate base. That is, the independent normal should be used on the logarithmic scale in order to construct the engine.

Objects from the Class

Objects can be created by using the IndependentNormal generator function. The object of class IndependentNormal contains the mean and standard deviation for the normal distribution

Slots

mu: see corresponding argument above
sigma: see corresponding argument above

Methods

- alterMean(object, TRANSFORM, ...)** Takes an object of class IndependentNormal, loops over the mu slot, alters the mean as defined by TRANSFORM function, and returns an object of class IndependentNormal with altered mu.
- alterSD(object, TRANSFORM, ...)** Takes an object of class IndependentNormal, loops over the sigma slot, alters the standard deviation as defined by TRANSFORM function, and returns an object of class IndependentNormal with altered sigma.
- nrow(x)** Returns the number of genes (i.e. the length of the mu vector).
- rand(object, n, ...)** Generates $nrow(IndependentNormal) * n$ matrix representing gene expressions of n samples following the normal distribution captured in the object of IndependentNormal.
- summary(object, ...)** Prints out the number of independent normal random variables in the object of IndependentNormal.

```

makeDataTypes	<i>Discretize a Continuous Data Set to Mixed Types</i>
---------------	--------------------------------------------------------

Description

The `makeDataTypes` function allows the user to discretize a continuous data set generated from an engine of any type into binary, nominal, ordinal, or mixed-type data.

Usage

```
makeDataTypes(dataset, pCont, pBin, pCat, pNominal = 0.5,
              range = c(3, 9), exact = FALSE, inputRowsAreFeatures = TRUE)
getDataTypes(object)
getDaisyTypes(object)
```

Arguments

<code>dataset</code>	A matrix or dataframe of continuous data.
<code>pCont</code>	Non-negative, numeric probability equal to or between 0 and 1 describing desired percent frequency of continuous features.
<code>pBin</code>	Non-negative, numeric probability equal to or between 0 and 1 describing desired percent frequency of binary features.
<code>pCat</code>	Non-negative, numeric probability equal to or between 0 and 1 describing desired percent frequency of categorical features.
<code>pNominal</code>	Non-negative, numeric probability equal to or between 0 and 1 describing desired percent frequency of categorical features to be simulated as nominal.
<code>range</code>	A set of integers whose minimum and maximum determine the range of the number of levels to be associated with simulated categorical factors.
<code>exact</code>	A logical value; should the parameters <code>pCont</code> , <code>pBin</code> and <code>pCat</code> be treated as exact fractions to achieve or as probabilities.
<code>inputRowsAreFeatures</code>	Logical value indicating if features are to be simulated as rows (TRUE) or columns (FALSE).
<code>object</code>	An object of the <code>MixedTypeEngine</code> class.

Details

The `makeDataTypes` function is a critical step in the construction of a `MixedTypeEngine`, which is an object that is used to simulate clinical mixed-type data instead of gene expression data. The standard process, as illustrated in the example, involves (1) creating a `ClinicalEngine`, (2) generating a random data set from that engine, (3) adding noise, (4) setting the data types, and finally (5) creating the `MixedTypeEngine`.

The main types of data (continuous, binary, or categorical) are randomly assigned using the probability parameters `pCont`, `pBin`, and `pCat`. To choose the splitting point for the binary features, we

compute the bimodality index (Wang et al.). If that is significant, we split the data halfway between the two modes. Otherwise, we choose a random split point between 5% and 35%. Categorical data is also randomly assigned to ordinal or nominal based on the `pNominal` parameter. The number of levels is uniformly selected in the specified range, and the fraction of data points assigned to each level is selected from a Dirichlet distribution with $\alpha = c(20, 20, \dots, 20)$.

Value

A list containing:

<code>binned</code>	An object of class <code>data.frame</code> of simulated, mixed-type data.
<code>cutpoints</code>	An object of class "list". For each feature, data type, labels (if data are binary or categorical), and break points (if data are binary or categorical) are stored. Cutpoints can be passed to a MixedTypeEngine for storage and downstream use.

The `getDataTypes` function returns a character vector listing the type of data for each feature in a `MixedTypeEngine`. the `getDaisyTypes` function converts this vector to a list suitable for input to the [daisy](#) function in the `cluster` package.

Note

If `pCont`, `pBin`, and `pCat` do not sum to 1, they will be rescaled.

By default, categorical variables are simulated as a mixture of nominal and ordinal data. The remaining categorical features described by `pNominal` are simulated as ordinal.

MixedTypeEngine-class *The "MixedTypeEngine" Class*

Description

A MixedTypeEngine combines a ClinicalEngine (which defines the combinatorics of hits and block hyperparameters that determine cluster identities and behavior), a stored [ClinicalNoiseModel](#), and cutpoints for generating mixed type data generated by [makeDataTypes](#) into an object that can be used to re-generate downstream datasets with shared parameters.

Usage

```

MixedTypeEngine(ce, noise, cutpoints)
## S4 method for signature 'MixedTypeEngine'
rand(object, n, keepall = FALSE, ...)
## S4 method for signature 'MixedTypeEngine'
summary(object, ...)

```

Arguments

ce	Object of class ClinicalEngine (or a list; see Details).
noise	Object of class NoiseModel, preferably constructed using the function ClinicalNoiseModel. Alternatively, a list; see Details.
cutpoints	a list with the properties of the cutpoints element produced by the function makeDataTypes. Alternatively, a list; see Details.
object	object of class MixedTypeEngine
n	a non-negative integer
keepall	a logical value
...	additional arguments for generic functions.

Details

The MixedTypeEngine is a device for a parameter set used to generate a simulated set of clinical data which can be used to store these parameters and to generate related datasets downstream. Building a MixedTypeEngine requires many parameters. You can supply these parameters in multiple steps:

1. Construct a ClinicalEngine.
2. Construct a ClinicalNoiseModel.
3. Use randrand to generate a "raw" data set from the ClinicalEngine.
4. Use blur to add noise to the raw data.
5. Feed the noisy data into makeDataTypes to generate a mixed-type dataset, with cut points.
6. Pass the ClinicalEngine, ClinicalNoiseModel, and cutpoints into the MixedTypeEngine constructor.

The alternative method is to pass the parameters for Steps 1, 2, and 5 directly into the MixedTypeEngine directly, as lists, and it will carry out steps 3-5 automatically. Note, however, that instead of passing a dataset to be used by the makeDataTypes function, you instead set the value of N to the desired number of patients used during construction. Also, if you use the explicit steps, you can save the intermediate data sets that are generated. If you simply pass all of the parameters to the constructor, those intermediate data sets are discarded, and you must generate a new data set using rand.

Objects from the Class

Objects can be created by a direct call to [new](#), though using the constructor MixedTypeEngine is preferred.

Methods

rand(object, n, keepall, ...) Generates $nrow(Engine) * n$ matrix representing clinical features of n patients following the underlying distribution, noise, and data discretization pattern captured in the object of MixedTypeEngine. If keepall == TRUE, it returns a list containing a data frame named clinical and three data matrices called raw, noisy, and binned. If keepall == FALSE, then only the clinical and binned components are returned.

summary(object, ...) Prints a summary of the object.

 MVN-class

The "MVN" Class

Description

The MVN class is a tool used to generate gene expressions that follow multivariate normal distribution.

Usage

```

MVN(mu, Sigma, tol = 1e-06)
covar(object)
correl(object)
## S4 method for signature 'MVN'
alterMean(object, TRANSFORM, ...)
## S4 method for signature 'MVN'
alterSD(object, TRANSFORM, ...)
## S4 method for signature 'MVN'
nrow(x)

```

```
## S4 method for signature 'MVN'
rand(object, n, ...)
## S4 method for signature 'MVN'
summary(object, ...)
```

Arguments

<code>mu</code>	numeric vector representing k -dimensional means
<code>Sigma</code>	numeric k -by- k covariance matrix containing the measurement of the linear coupling between every pair of random vectors
<code>tol</code>	numeric scalar roundoff error that will be tolerated when assessing the singularity of the covariance matrix
<code>object, x</code>	object of class MVN
<code>TRANSFORM</code>	function that takes a vector of mean expression or standard deviation and returns a transformed vector that can be used to alter the appropriate slot of the object.
<code>n</code>	numeric scalar representing number of samples to be simulated
<code>...</code>	extra arguments for generic or plotting routines

Details

The implementation of MVN class is designed for efficiency when generating new samples, since we expect to do this several times. Basically, this class separates the `mvnorm` function from the **MASS** package into several steps. The computationally expensive step (when the dimension is large) is the eigenvector decomposition of the covariance matrix. This step is performed at construction and the pieces are stored in the object. The `rand` method for MVN objects contains the second half of the `mvnorm` function.

Note that we typically work on expression values after taking the logarithm to some appropriate base. That is, the multivariate normal should be used on the logarithmic scale in order to construct an engine.

The `alterMean` method for an MVN simply replaces the appropriate slot by the transformed vector. The `alterSD` method for an MVN is trickier, because of the way the data is stored. In order to have some hope of getting this correct, we work in the space of the covariance matrix, *Sigma*. If we let R denote the correlation matrix and let Δ be the diagonal matrix whose entries are the individual standard deviations, then $Sigma = \Delta R \Delta$. So, we can change the standard deviations by replacing Δ in this product. We then construct a new MVN object with the old mean vector and the new covariance matrix.

The `covar` and `correl` functions, respectively, calculate the covariance matrix and correlation matrix that underly the covariance matrix for the objects of class MVN. We have four assertions as shown below, which are tested in the examples section:

1. `covar` should return the same matrix that was used in the function call to construct the MVN object.
2. After applying an `alterMean` method, the covariance matrix is unchanged.
3. The diagonal of the correlation matrix consists of all ones.
4. After applying an `alterMean` or an `alterSD` method, the correlation matrix is unchanged.

Objects from the Class

Although objects of the class can be created by a direct call to `new`, the preferred method is to use the MVN generator function.

Slots

`mu`: numeric vector containing the k -dimensional means

`lambda`: numeric vector containing the square roots of the eigenvalues of the covariance matrix

`half`: numeric matrix with $k * k$ dimensions whose columns contain the eigenvectors of the covariance matrix

Methods

alterMean(object, TRANSFORM, ...) Takes an object of class MVN, loops over the `mu` slot, alters the mean as defined by TRANSFORM function, and returns an object of class MVN with altered `mu`.

alterSD(object, TRANSFORM, ...) Takes an object of class MVN, works on the diagonal matrix of the covariance matrix, alters the standard deviation as defined by TRANSFORM function, and reconstructs an object of class MVN with the old `mu` and reconstructed covariance matrix.

nrow(x) Returns the number of genes (i.e, the length of the `mu` vector).

rand(object, n, ...) Generates $nrow(MVN) * n$ matrix representing gene expressions of n samples following the multivariate normal distribution captured in the object of MVN.

summary(object, ...) Prints out the number of multivariate normal random variables in the object of MVN.

covar(object) Returns the covariance matrix of the object of class MVN.

correl(object) Returns the correlation matrix of the object of class MVN.

```

nComponents-method *Method "nComponents"*

Description

nComponents is a generic function, analogous to 'nrow' or 'ncol', that reports the number of components of an "engine".

Usage

```
## S4 method for signature 'ANY'
nComponents(object, ...)
```

Arguments

object	an object from which the number of components is desired
...	additional arguments affecting the number of components produced

Value

Returns a nonnegative integer (scalar).

Author(s)

Kevin R. Coombes <krc@silicovore.com>, Caitlin E. Coombes <caitlin.coombes@osumc.edu>

 NoiseModel-class *The "NoiseModel" Class*

Description

A NoiseModel represents the additional machine noise that is layered on top of any biological variability when measuring the gene expression in a set of samples.

Usage

```
NoiseModel(nu, tau, phi)
## S4 method for signature 'NoiseModel'
blur(object, x, ...)
## S4 method for signature 'NoiseModel'
summary(object, ...)
```

Arguments

nu	The mean value for the additive noise
tau	The standard deviation for the additive noise
phi	The standard deviation for the multiplicative noise. Note that the mean of the multiplicative noise is set to \emptyset .
object	object of class NoiseModel
x	The data matrix containing true signal from the gene expression
...	extra arguments affecting the blur method applied

Details

We model both additive and multiplicative noise, so that the observed expression of gene g in sample i is given by: $Y_{gi} = S_{g} \exp(H_{gi}) + E_{gi}$, where Y_{gi} = observed expression, S_{gi} = true biological signal, $H_{gi} \sim N(0, \text{phi})$ defines the multiplicative noise, and $E_{gi} \sim N(\text{nu}, \text{tau})$ defines the additive noise. Note that we allow a systematic offset/bias in the additive noise model.

Methods

blur(object, x, ...) Adds and multiplies random noise to the data matrix x containing the true signal from the gene expression.

summary(object, ...) Prints a summary of the object.

NormalVsCancer

Simulating Cancer Versus Normal Datasets

Description

These functions are useful for simulating data that compares a homogeneous "cancer" group to a homogeneous "normal" group of samples.

Usage

```
NormalVsCancerModel(nBlocks, survivalModel=NULL, name="NormalVsCancer")
NormalVsCancerEngine(nBlocks, hyperp)
```

Arguments

nBlocks	scalar integer representing number of correlated blocks that are differentially expressed between cancer and normal
survivalModel	a SurvivalModel object
name	character string specifying name of the object being created
hyperp	object of class BlockHyperParameters that describes the block correlation structure.

Details

The simplest simulation model assumes that we are comparing two homogeneous groups.

dset <- rand(engine, 10, balance=TRUE)
```

rand-method	<i>Method "rand"</i>
-------------	----------------------

Description

rand is a generic function used to produce random vectors from the distribution defined by various objects. The generic function invokes particular [methods](#) which depend on the [class](#) of the first argument.

Usage

```
## S4 method for signature 'ANY'
rand(object, n, ...)
```

Arguments

object	an object from which random numbers from a distribution is desired
n	numeric scalar specifying quantity of random numbers
...	additional arguments affecting the random numbers produced

Value

The form of the value returned by rand depends on the class of its argument. See the documentation of the particular methods for details of what is produced by that method.

Author(s)

Kevin R. Coombes <krc@silicovore.com>,

SurvivalModel-class *The "SurvivalModel" Class*

Description

A SurvivalModel class represents the information for simulating survival times for each patient.

Usage

```
SurvivalModel(baseHazard = 1/5,
              accrual = 5,
              followUp = 1,
              units = 12,
              unitName = "months")
## S4 method for signature 'SurvivalModel'
rand(object, n, beta = NULL, ...)
```

Arguments

baseHazard	numeric scalar describing the underlying hazard rate at baseline levels of covariates
accrual	numeric scalar representing number of patient accrual years
followUp	numeric scalar representing length of follow up, in years
units	numeric scalar representing number of units per year where units are specified by unitName
unitName	character string representing the unit argument type
object	object of class SurvivalModel
n	numeric scalar specifying quantity of random numbers
beta	numeric vector specifying beta parameters for patients
...	extra arguments for generic routines

Value

The SurvivalModel generator returns an object of class SurvivalModel.

The rand method returns a data.frame with components:

LFU	time to event
Event	whether the data is censored

Objects from the Class

Although objects of the class can be created by a direct call to `new`, the preferred method is to use the SurvivalModel generator function.

Slots

baseHazard: see corresponding argument above
accrual: see corresponding argument above
followUp: see corresponding argument above
units: see corresponding argument above
unitName: see corresponding argument above

Methods

rand(object, n, beta, ...) Simulate survival data for n patients given beta.

Examples

```
showClass("SurvivalModel")
sm <- SurvivalModel()
## Generate data from base model
outcome <- rand(sm, 100)
summary(outcome)
## Generate data from five classes with different beta parameters
beta <- rep(rnorm(5, 0, 2), each = 20)
outcome <- rand(sm, 100, beta = beta)
summary(outcome)
```

transforms

Transform functions

Description

normalOffset is a function that can be used as the TRANSFORM argument in an alterMean operation, which adds an offset to each value in the mean where the offset is chosen from a normal distribution.

invGammaMultiple is a function that can be used as the TRANSFORM argument in an alterSD operation, which multiplies each standard deviation by a positive value chosen from an inverse gamma distribution with parameters shape and scale.

Usage

```
normalOffset(x, delta, sigma)
invGammaMultiple(x, shape, rate)
```

Arguments

x	numeric vector of mean expression or standard deviation defined in the object
delta, sigma	numeric vector used as mean and/or sd parameters specifying the normal distribution
shape, rate	numeric vector used as shape and/or rate parameters specifying the gamma distribution. Must be positive.

Value

`normalOffset` returns a new vector, TO each element of which is added aN offset chosen from a normal distribution with parameters mean and sd.

`invGammaMultiple` returns a new vector, each element of which is multiplied by a positive value chosen from an inverse gamma distribution with parameters shape and scale.
