# Package 'survPen'

March 8, 2025

**Title** Multidimensional Penalized Splines for (Excess) Hazard Models, Relative Mortality Ratio Models and Marginal Intensity Models

Version 2.0.2

**Description** Fits (excess) hazard, relative mortality ratio or marginal intensity models with multidimensional penalized splines allowing for

time-dependent effects, non-linear effects and interactions between several continuous covariates. In survival and net survival analysis, in addition to modelling the effect of time (via the baseline hazard), one has often to deal with several continuous covariates and model their functional forms, their time-dependent effects, and their interactions. Model specification becomes therefore a complex problem and penalized regression splines represent an appealing solution to that problem as splines offer the required flexibility while penalization limits overfitting issues. Current implementations of penalized survival models can be slow or unstable and sometimes lack some key features like taking into account expected mortality to provide net survival and excess hazard estimates. In contrast, survPen provides an automated, fast, and stable implementation (thanks to explicit calculation of the derivatives of the likelihood) and offers a unified framework for multidimensional penalized hazard and excess hazard models. Later versions (>2.0.0) include penalized models for relative mortality ratio, and marginal intensity in recurrent event setting. survPen may be of interest to those who 1) analyse any kind of time-to-event data: mortality, disease relapse, machinery breakdown, unemployment, etc 2) wish to describe the associated hazard and to understand which predictors impact its dynamics,

3) wish to model the relative mortality ratio between a cohort and a reference population, 4) wish to describe the marginal intensity for recurrent event data. See Fauvernier et al. (2019a) <doi:10.21105/joss.01434> for an overview of the package and Fauvernier et al. (2019b) <doi:10.1111/rssc.12368> for the method.

# Description

colSums of a matrix

# Usage

colSums2(Mat)

# Arguments

Mat a matrix.

# Value

colSums(Mat)

4 constraint

constraint

Sum-to-zero constraint

### **Description**

Applies the sum-to-zero constraints to design and penalty matrices.

# Usage

```
constraint(X, S, Z = NULL)
```

### Arguments

Χ	A design	matrix
---	----------	--------

- S A penalty matrix or a list of penalty matrices
- Z A list of sum-to-zero constraint matrices; default is NULL

### Value

List of objects with the following items:

- X Design matrix
- S Penalty matrix or list of penalty matrices
- Z List of sum-to-zero constraint matrices

# **Examples**

```
library(survPen)
set.seed(15)

X <- matrix(rnorm(10*3),nrow=10,ncol=3)
S <- matrix(rnorm(3*3),nrow=3,ncol=3) ; S <- 0.5*( S + t(S))

# applying sum-to-zero constraint to a desgin matrix and a penalty matrix constr <- constraint(X,S)</pre>
```

cor.var 5

cor.var	Implementation of the corrected variance Vc	

# Description

Takes the model at convergence and calculates the variance matrix corrected for smoothing parameter uncertainty

### Usage

```
cor.var(model)
```

# Arguments

model survPen object, see survPen.fit for details

### Value

survPen object with corrected variance Vc

crs	Bases for cubic regression splines (equivalent to "cr" in mgcv)

# Description

Builds the design matrix and the penalty matrix for cubic regression splines.

# Usage

```
crs(x, knots = NULL, df = 10, intercept = TRUE)
```

# Arguments

X	Numeric vector
knots	Numeric vectors that specifies the knots of the splines (including boundaries); default is NULL
df	numeric value that indicates the number of knots desired (or degrees of freedom) if knots=NULL; default is $10$
intercept	if FALSE, the intercept is excluded from the basis; default is TRUE

### **Details**

See package mgcv and section 4.1.2 of Wood (2006) for more details about this basis

6 crs.FP

# Value

List of three elements

bs design matrix pen penalty matrix

knots vector of knots (specified or calculated from df)

### References

Wood, S. N. (2006), Generalized additive models: an introduction with R. London: Chapman & Hall/CRC.

# **Examples**

```
x <- seq(1,10,length=100)
# natural cubic spline with 3 knots
crs(x,knots=c(1,5,10))</pre>
```

crs.FP

Penalty matrix constructor for cubic regression splines

### **Description**

constructs the penalty matrix associated with cubic regression splines basis. This function is called inside crs.

### Usage

```
crs.FP(knots, h)
```

# Arguments

knots Numeric vectors that specifies the knots of the splines (including boundaries)

h vector of knots differences (corresponds to diff(sort(knots)))

### Value

List of two elements:

F.mat matrix used in function crs for basis construction

P.mat penalty matrix

CumulHazard 7

### **Examples**

```
library(survPen)
# construction of the penalty matrix using a sequence of knots
knots <- c(0,0.25,0.5,0.75,1)
diff.knots <- diff(knots)
crs.FP(knots,diff.knots)</pre>
```

CumulHazard

Cumulative hazard (integral of hazard) only

# Description

Cumulative hazard (integral of hazard) only

### Usage

```
CumulHazard(X_GL, weights, tm, n_legendre, n, beta, is_pwcst, pwcst_weights)
```

### **Arguments**

X_GL	list of matrices (length(X.GL)=n.legendre) for Gauss-Legendre quadrature
weights	vector of weights for Gauss-Legendre integration on [-1;1]
tm	vector of midpoints times for Gauss-Legendre integration; $tm = 0.5*(t1 - t0)$
n_legendre	number of nodes for Gauss-Legendre quadrature
n	number of individuals in the dataset
beta	vector of estimated regression parameters
is_pwcst	True if there is a piecewise constant baseline specified. False otherwise
pwcst_weights	if is_pwcst is TRUE, matrix of weights giving the time contribution of each

in is\_pwest is TROD, matrix of weights giving the time contribution

individual on each sub-interval. Otherwise NULL

#### Value

cumulative hazard (integral of hazard)

8 DerivCumulHazard

datCancer

Patients diagnosed with cervical cancer

# Description

A simulated dataset containing the follow-up times of 2000 patients diagnosed with cervical cancer between 1990 and 2010. End of follow-up is June 30th 2013. The variables are as follows:

- begin. beginning of follow-up. For illustration purposes about left truncation only (0–1)
- fu. follow-up time in years (0–5)
- age. age at diagnosis in years, from 21.39 to 99.33
- yod. decimal year of diagnosis, from 1990.023 to 2010.999
- dead. censoring indicator (1 for dead, 0 for censored)
- rate. expected mortality rate (from overall mortality of the general population) (0–0.38)

### Usage

```
data(datCancer)
```

#### **Format**

A data frame with 2000 rows and 6 variables

DerivCumulHazard

Cumulative hazard (integral of hazard) and its first and second derivatives wrt regression parameters beta

### **Description**

Cumulative hazard (integral of hazard) and its first and second derivatives wrt regression parameters beta

### Usage

```
DerivCumulHazard(
   X_GL,
   weights,
   tm,
   n_legendre,
   n,
   p,
   beta,
   expected,
   type,
   is_pwcst,
   pwcst_weights
)
```

deriv\_R

### **Arguments**

X\_GL list of matrices (length(X.GL)=n.legendre) for Gauss-Legendre quadrature

weights vector of weights for Gauss-Legendre integration on [-1;1]

tm vector of midpoints times for Gauss-Legendre integration; tm = 0.5\*(t1 - t0)

n\_legendre number of nodes for Gauss-Legendre quadrature

n number of individuals in the dataset
p number of regression parameters

beta vector of estimated regression parameters

expected vector of expected hazard rates type "net", "overall" or "mult"

is\_pwcst True if there is a piecewise constant baseline specified. False otherwise

pwcst\_weights if is.pwcst is TRUE, matrix of weights giving the time contribution of each in-

dividual on each sub-interval. Otherwise NULL

#### Value

List of objects with the following items:

integral cumulative hazard (integral of hazard)

f.first first derivative of cumulative hazard wrt beta

f.second second derivative of cumulative hazard wrt beta

deriv\_R Derivative of a Choleski factor

### **Description**

Derivative of a Choleski factor

### Usage

```
deriv_R(deriv_Vp, p, R1)
```

### **Arguments**

deriv\_Vp derivatives of the Bayesian covariance matrix wrt rho (log smoothing parame-

ters).

p number of regression parameters

R1 Choleski factor of Vp

#### Value

a list containing the derivatives of R1 wrt rho (log smoothing parameters)

10 design.matrix

design.matrix	Design matrix for the model needed in Gauss-Legendre quadrature

# Description

Builds the design matrix for the whole model when the sum-to-zero constraints are specified. The function is called inside model.cons for Gauss-Legendre quadrature.

# Usage

```
design.matrix(
  formula,
  data.spec,
  t1.name,
  Z.smf,
  Z.tensor,
  Z.tint,
  list.smf,
  list.tensor,
  list.tint,
  list.rd
)
```

# **Arguments**

formula	formula object identifying the model
data.spec	data frame that represents the environment from which the covariate values and knots are to be calculated
t1.name	name of the vector of follow-up times
Z.smf	List of matrices that represents the sum-to-zero constraint to apply for $\operatorname{smf}$ splines
Z.tensor	List of matrices that represents the sum-to-zero constraint to apply for tensor splines
Z.tint	List of matrices that represents the sum-to-zero constraint to apply for tint splines
list.smf	List of all smf.smooth.spec objects contained in the model
list.tensor	List of all tensor.smooth.spec objects contained in the model
list.tint	List of all tint.smooth.spec objects contained in the model
list.rd	List of all rd.smooth.spec objects contained in the model

### Value

design matrix for the model

expected.table 11

### **Examples**

```
library(survPen)
# standard spline of time with 4 knots
data <- data.frame(time=seq(0,5,length=100),event=1,t0=0)</pre>
form \leftarrow smf(time,knots=c(0,1,3,5))
t1 <- eval(substitute(time), data)</pre>
t0 <- eval(substitute(t0), data)</pre>
event <- eval(substitute(event), data)</pre>
# Setting up the model
model.c <- model.cons(form,lambda=0,data.spec=data,t1=t1,t1.name="time",</pre>
t0=rep(0,100),t0.name="t0",event=event,event.name="event",
expected=rep(0,100),expected.name=NULL,type="overall",n.legendre=20,
cl="survPen(form,data,t1=time,event=event)",beta.ini=NULL)
# Retrieving the sum-to-zero constraint matrices and the list of knots
Z.smf <- model.c$Z.smf ; list.smf <- model.c$list.smf</pre>
# Calculating the design matrix
design.M <- design.matrix(form,data.spec=data,t1.name="time",Z.smf=Z.smf,list.smf=list.smf,</pre>
Z.tensor=NULL,Z.tint=NULL,list.tensor=NULL,list.tint=NULL,list.rd=NULL)
```

expected.table

French women mortality table

### **Description**

French women mortality table to serve as example of reference/expected mortality in excess hazard and relative mortality ratio models The data come from the human mortality databse website: https://www.mortality.org/Country/Country?cntr=FRATNP

- Age. Age group for 1-year interval from exact age x to just before exact age x+1 (0-110+)
- Year. Calendar Year (1816-2021)
- mx. Central death rate between ages x and x+1

### Usage

```
data(expected.table)
```

### **Format**

A data frame with 22866 rows and 3 variables

12 grad\_rho

grad_rho Gradient vector of LCV and LAML wrt rho (log ters)
---

# Description

Gradient vector of LCV and LAML wrt rho (log smoothing parameters)

# Usage

```
grad_rho(
 X_GL,
 GL_temp,
 haz_GL,
 deriv_rho_beta,
 weights,
  tm,
  nb_smooth,
 n_legendre,
 S_list,
  {\tt temp\_LAML},
  ۷p,
  S_beta,
 beta,
  inverse_new_S,
  temp_deriv3,
  event,
  expected,
  type,
  Vе,
 mat_temp,
 method
)
```

### Arguments

X_GL	list of matrices (length(X.GL)=n.legendre) for Gauss-Legendre quadrature
GL_temp	list of vectors used to make intermediate calculations and save computation time
haz_GL	list of all the matrix-vector multiplications $X.GL[[i]]\%*\%$ beta for Gauss Legendre integration in order to save computation time
deriv_rho_beta	firt derivative of beta wrt rho (implicit differentiation)
weights	vector of weights for Gauss-Legendre integration on [-1;1]
tm	vector of midpoints times for Gauss-Legendre integration; $tm = 0.5*(t1 - t0)$

grad\_rho\_mult 13

nb\_smooth number of smoothing parameters
p number of regression parameters

n\_legendre number of nodes for Gauss-Legendre quadrature

S\_list List of all the rescaled penalty matrices multiplied by their associated smoothing

parameters

temp\_LAML temporary matrix used when method="LAML" to save computation time

Vp Bayesian covariance matrix

S\_beta List such that S\_beta[[i]]=S\_list[[i]]%\*%beta beta vector of estimated regression parameters

inverse\_new\_S inverse of the penalty matrix X design matrix for the model

temp\_deriv3 temporary matrix for third derivatives calculation when type="net" to save com-

putation time

event vector of right-censoring indicators
expected vector of expected hazard rates

type "net" or "overall"

Ve frequentist covariance matrix

mat\_temp temporary matrix used when method="LCV" to save computation time

method criterion used to select the smoothing parameters. Should be "LAML" or "LCV";

default is "LAML"

#### Value

List of objects with the following items:

grad\_rho gradient vector of LCV or LAML

deriv\_rho\_inv\_Hess\_beta

List of first derivatives of Vp wrt rho

deriv\_rho\_Hess\_unpen\_beta

List of first derivatives of the Hessian of the unpenalized log-likelihood wrt rho

grad\_rho\_mult Gradient vector of LCV and LAML wrt rho (log smoothing param-

eters). Version for multiplicative decomposition: relative mortality

ratio model

### **Description**

Gradient vector of LCV and LAML wrt rho (log smoothing parameters). Version for multiplicative decomposition : relative mortality ratio model

14 grad\_rho\_mult

### Usage

```
grad_rho_mult(
  X_GL,
  GL_temp,
 haz_GL,
  deriv_rho_beta,
 weights,
  tm,
  nb_smooth,
  n_legendre,
  S_list,
  temp_LAML,
  ۷p,
  S_beta,
  beta,
  inverse_new_S,
  Χ,
  event,
  expected,
  Vе,
 mat_temp,
 method
)
```

### **Arguments**

X_GL	list of matrices (length(X.GL)=n.legendre) for Gauss-Legendre quadrature
GL_temp	list of vectors used to make intermediate calculations and save computation time
haz_GL	list of all the matrix-vector multiplications $X.GL[[i]]\%*\%$ beta for Gauss Legendre integration in order to save computation time
deriv_rho_beta	firt derivative of beta wrt rho (implicit differentiation)
weights	vector of weights for Gauss-Legendre integration on [-1;1]

tm vector of midpoints times for Gauss-Legendre integration; tm = 0.5\*(t1 - t0)

nb\_smooth number of smoothing parameters
p number of regression parameters

n\_legendre number of nodes for Gauss-Legendre quadrature

S\_list List of all the rescaled penalty matrices multiplied by their associated smoothing

parameters

temp\_LAML temporary matrix used when method="LAML" to save computation time

Vp Bayesian covariance matrix

S\_beta List such that S\_beta[[i]]=S\_list[[i]]%\*%beta beta vector of estimated regression parameters

inverse\_new\_S inverse of the penalty matrix

HazGL 15

X design matrix for the model

event vector of right-censoring indicators
expected vector of expected hazard rates
Ve frequentist covariance matrix

mat\_temp temporary matrix used when method="LCV" to save computation time

method criterion used to select the smoothing parameters. Should be "LAML" or "LCV";

default is "LAML"

#### Value

List of objects with the following items:

grad\_rho gradient vector of LCV or LAML

deriv\_rho\_inv\_Hess\_beta

List of first derivatives of Vp wrt rho

deriv\_rho\_Hess\_unpen\_beta

List of first derivatives of the Hessian of the unpenalized log-likelihood wrt rho

HazGL Gauss-Legendre evaluations

### **Description**

Gauss-Legendre evaluations

### Usage

```
HazGL(X_GL, n_legendre, beta)
```

#### **Arguments**

X\_GL list of matrices (length(X.GL)=n.legendre) for Gauss-Legendre quadrature

n\_legendre number of nodes for Gauss-Legendre quadrature

beta vector of estimated regression parameters

#### Value

list of all the matrix-vector multiplications X.GL[[i]]%\*% beta for Gauss Legendre integration in order to save computation time

16 Hess\_rho

HeartFailure

Patients with heart failure at risk of recurrent hospitalization events

### Description

A simulated dataset containing 3 068 observations (2 268 events) in 800 patients with heart failure. The dataset is based on hfaction\_cpx12 dataset from package WA. The variables are as follows:

- id. patient identification number
- treatment. treatment=0 for control and treatment=1 for exercise training
- t0. beginning of follow-up for a given event
- t1. end of follow-up for a given event (up to 3.27 years)
- enum. event identification number for a given patient (between 1 and 6 events per patient)
- event. event indicator (1 for hospitalization, 0 for censored)

### Usage

```
data(HeartFailure)
```

### **Format**

A data frame with 3 068 rows and 6 variables

Hess\_rho

Hessian matrix of LCV and LAML wrt rho (log smoothing parameters)

### Description

Hessian matrix of LCV and LAML wrt rho (log smoothing parameters)

# Usage

```
Hess_rho(
   X_GL,
   X_GL_Q,
   GL_temp,
   haz_GL,
   deriv2_rho_beta,
   deriv_rho_beta,
   weights,
   tm,
   nb_smooth,
   p,
   n_legendre,
```

Hess\_rho 17

```
deriv_rho_inv_Hess_beta,
  deriv_rho_Hess_unpen_beta,
  S_list,
 minus_eigen_inv_Hess_beta,
  temp_LAML,
  temp_LAML2,
  ۷p,
  S_beta,
  beta,
  inverse_new_S,
 Χ,
  X_Q,
  temp_deriv3,
  temp_deriv4,
  event,
  expected,
  type,
  ۷e,
  deriv_rho_Ve,
 mat_temp,
  deriv_mat_temp,
  eigen_mat_temp,
 method
)
```

### Arguments

X\_GL list of matrices (length(X.GL)=n.legendre) for Gauss-Legendre quadrature list of transformed matrices from X\_GL in order to calculate only the diagonal X\_GL\_Q of the fourth derivative of the likelihood list of vectors used to make intermediate calculations and save computation time GL\_temp haz\_GL list of all the matrix-vector multiplications X.GL[[i]]%\*%beta for Gauss Legendre integration in order to save computation time deriv2\_rho\_beta second derivatives of beta wrt rho (implicit differentiation) deriv\_rho\_beta firt derivatives of beta wrt rho (implicit differentiation) weights vector of weights for Gauss-Legendre integration on [-1;1] vector of midpoints times for Gauss-Legendre integration; tm = 0.5\*(t1 - t0)tm number of smoothing parameters nb\_smooth number of regression parameters n\_legendre number of nodes for Gauss-Legendre quadrature deriv\_rho\_inv\_Hess\_beta list of first derivatives of Vp wrt rho deriv\_rho\_Hess\_unpen\_beta list of first derivatives of Hessian of unpenalized log likelihood wrt rho

18 Hess\_rho\_mult

S\_list List of all the rescaled penalty matrices multiplied by their associated smoothing

parameters

minus\_eigen\_inv\_Hess\_beta

vector of eigenvalues of Vp

temp\_LAML temporary matrix used when method="LAML" to save computation time temp\_LAML2 temporary matrix used when method="LAML" to save computation time

Vp Bayesian covariance matrix

S\_beta List such that S\_beta[[i]]=S\_list[[i]]%\*%beta beta vector of estimated regression parameters

inverse\_new\_S inverse of the penalty matrix X design matrix for the model

X\_Q transformed design matrix in order to calculate only the diagonal of the fourth

derivative of the likelihood

temp\_deriv3 temporary matrix for third derivatives calculation when type="net" to save com-

putation time

temp\_deriv4 temporary matrix for fourth derivatives calculation when type="net" to save

computation time

event vector of right-censoring indicators
expected vector of expected hazard rates

type "net" or "overall"

Ve frequentist covariance matrix deriv\_rho\_Ve list of derivatives of Ve wrt rho

mat\_temp temporary matrix used when method="LCV" to save computation time

deriv\_mat\_temp list of derivatives of mat\_temp wrt rho
eigen\_mat\_temp vector of eigenvalues of mat temp

method criterion used to select the smoothing parameters. Should be "LAML" or "LCV";

default is "LAML"

#### Value

Hessian matrix of LCV or LAML wrt rho

Hess\_rho\_mult Hessian matrix of LCV and LAML wrt rho (log smoothing parame-

ters). Version for multiplicative decomposition: relative mortality

ratio model

#### **Description**

Hessian matrix of LCV and LAML wrt rho (log smoothing parameters). Version for multiplicative decomposition: relative mortality ratio model

Hess\_rho\_mult 19

# Usage

```
Hess_rho_mult(
 X_GL,
  X_GL_Q,
 GL_temp,
 haz_GL,
  deriv2_rho_beta,
  deriv_rho_beta,

 deriv_mat_temp,
  eigen_mat_temp,
 {\tt method}
)
```

# Arguments

X_GL	list of matrices (length(X.GL)=n.legendre) for Gauss-Legendre quadrature	
X_GL_Q	list of transformed matrices from $X\_GL$ in order to calculate only the diagonal of the fourth derivative of the likelihood	
GL_temp	list of vectors used to make intermediate calculations and save computation time	
haz_GL	list of all the matrix-vector multiplications X.GL[[i]]%*%beta for Gauss Legendre integration in order to save computation time	
deriv2_rho_beta		
	second derivatives of beta wrt rho (implicit differentiation)	
deriv_rho_beta	firt derivatives of beta wrt rho (implicit differentiation)	
weights	vector of weights for Gauss-Legendre integration on [-1;1]	

20 Hess\_rho\_mult

tm vector of midpoints times for Gauss-Legendre integration; tm = 0.5\*(t1 - t0)

nb\_smooth number of smoothing parameters
p number of regression parameters

n\_legendre number of nodes for Gauss-Legendre quadrature

deriv\_rho\_inv\_Hess\_beta

list of first derivatives of Vp wrt rho

deriv\_rho\_Hess\_unpen\_beta

list of first derivatives of Hessian of unpenalized log likelihood wrt rho

S\_list List of all the rescaled penalty matrices multiplied by their associated smoothing

parameters

minus\_eigen\_inv\_Hess\_beta

vector of eigenvalues of Vp

temp\_LAML temporary matrix used when method="LAML" to save computation time

temp\_LAML2 temporary matrix used when method="LAML" to save computation time

Vp Bayesian covariance matrix

S\_beta List such that S\_beta[[i]]=S\_list[[i]]%\*%beta

beta vector of estimated regression parameters

inverse\_new\_S inverse of the penalty matrix
X design matrix for the model

X\_Q transformed design matrix in order to calculate only the diagonal of the fourth

derivative of the likelihood

event vector of right-censoring indicators

expected vector of expected hazard rates

Ve frequentist covariance matrix

deriv\_rho\_Ve list of derivatives of Ve wrt rho

mat\_temp temporary matrix used when method="LCV" to save computation time

deriv\_mat\_temp list of derivatives of mat\_temp wrt rho

eigen\_mat\_temp vector of eigenvalues of mat\_temp

method criterion used to select the smoothing parameters. Should be "LAML" or "LCV";

default is "LAML"

### Value

Hessian matrix of LCV or LAML wrt rho

instr 21

i	n	ς	+	r

Position of the nth occurrence of a string in another one

### **Description**

Returns the position of the nth occurrence of str2 in str1. Returns 0 if str2 is not found. This code was first suggested by Abdelmonem Mahmoud Amer in https://stackoverflow.com/a/33005653/5421090

### Usage

```
instr(str1, str2, startpos = 1, n = 1)
```

### Arguments

str1 main string in which str2 is to be found

str2 substring contained in str1

startpos starting position in str1; default is 1

n which occurrence is to be found; default is 1

### Value

number representing the nth position of str2 in str1

### **Examples**

```
library(survPen) instr("character\ test\ to\ find\ the\ position\ of\ the\ third\ letter\ r","r",n=3)
```

inv.repam

Reverses the initial reparameterization for stable evaluation of the log determinant of the penalty matrix

### **Description**

Transforms the final model by reversing the initial reparameterization performed by repam. Derives the corrected version of the Bayesian covariance matrix

### Usage

```
inv.repam(model, X.ini, S.pen.ini)
```

22 model.cons

### **Arguments**

model survPen object, see survPen.fit for details

X.ini initial design matrix (before reparameterization)

S.pen.ini initial penalty matrices

### Value

survPen object with standard parameterization

list.wicss

List of ICSS standards for age-standardization of cancer (net) survival

### Description

Four data frames are available in the list: 1, 2, 3 and "prostate". Each one corresponds to certain types of cancer. Details can be found in Corazzieri et al. (2004) (10.1016/j.ejca.2004.07.002) or at (in French): https://www.santepubliquefrance.fr/docs/survie-des-personnes-atteintes-de-canceren-france-metropolitaine-1989-2018-materiel-et-methodes For each data frame, the variables are as follows:

- AgeClass. Age classes considered. Closed on the left and open on the right.
- AgeWeights. Weights associated with each age class

### Usage

```
data(list.wicss)
```

#### **Format**

A list containing four data frames of 5 rows and 2 variables each

model.cons

Design and penalty matrices for the model

### **Description**

Sets up the model before optimization. Builds the design matrix, the penalty matrix and all the design matrices needed for Gauss-Legendre quadrature.

model.cons 23

### Usage

```
model.cons(
  formula,
  lambda,
  data.spec,
  t1,
  t1.name,
  t0,
  t0.name,
  event,
  event.name,
  expected,
  expected.name,
  type,
  n.legendre,
  cl,
 beta.ini
)
```

### **Arguments**

formula object identifying the model

lambda vector of smoothing parameters

data frame that represents the environment from which the covariate values and

knots are to be calculated

t1 vector of follow-up times t1.name name of t1 in data.spec

to vector of origin times (usually filled with zeros)

t0.name name of t0 in data.spec
event vector of censoring indicators
event.name name of event in data.spec
expected vector of expected hazard

expected.name name of expected in data.spec

type "net" or "overall"

n.legendre number of nodes for Gauss-Legendre quadrature

cl original survPen call

beta.ini initial set of regression parameters

### Value

List of objects with the following items:

cl original survPen call type "net", "overall", or "mult"

24 model.cons

n.legendre	number of nodes for Gauss-Legendre quadrature. If is.pwcst is TRUE, for simplicity of implementation, n.legendre actually corresponds to the number of sub-intervals
n	number of individuals
р	number of parameters
X.para	design matrix associated with fully parametric parameters (unpenalized)
X.smooth	design matrix associated with the penalized parameters
Χ	design matrix for the model
is.pwcst	TRUE if there is a piecewise constant (excess) hazard specification. In that case the cumulative hazard can be derived without Gauss-Legendre quadrature
pwcst.breaks	if is.pwcst is TRUE, vector of breaks defining the sub-intervals on which the hazard is constant. Otherwise NULL.
pwcst.weights	if is.pwcst is TRUE, matrix of weights giving the time contribution of each individual on each sub-interval. Otherwise NULL.
leg	list of nodes and weights for Gauss-Legendre integration on [-1;1] as returned by gauss.quad
X.GL	list of matrices (length(X.GL)=n.legendre) for Gauss-Legendre quadrature
S	penalty matrix for the model. Sum of the elements of S.list
S.scale	vector of rescaling factors for the penalty matrices
rank.S	rank of the penalty matrix
S.F	balanced penalty matrix as described in section 3.1.2 of (Wood,2016). Sum of the elements of S.F.list
U.F	Eigen vectors of S.F, useful for the initial reparameterization to separate penalized ad unpenalized subvectors. Allows stable evaluation of the log determinant of S and its derivatives
S.smf	List of penalty matrices associated with all "smf" calls
S.tensor	List of penalty matrices associated with all "tensor" calls
S.tint	List of penalty matrices associated with all "tint" calls
S.rd	List of penalty matrices associated with all "rd" calls
smooth.name.smf	
smooth.name.ter	List of names for the "smf" calls associated with S.smf nsor List of names for the "tensor" calls associated with S.tensor
smooth.name.tir	
	List of names for the "tint" calls associated with S.tint
smooth.name.rd	List of names for the "rd" calls associated with S.rd
S.pen	List of all the rescaled penalty matrices redimensioned to df.tot size. Every element of pen noted $pen[[i]]$ is made from a penalty matrix returned by $smooth.cons$ and is multiplied by the factor $S.scale=norm(X,type="I")^2/norm(pen[[i]],type="I")$
S.list	Equivalent to S.pen but with every element multiplied by its associated smoothing parameter

NR.beta 25

S.F.list	Equivalent to S.pen but with every element divided by its Frobenius norm
lambda	vector of smoothing parameters
df.para	degrees of freedom associated with fully parametric terms (unpenalized)
df.smooth	degrees of freedom associated with penalized terms
df.tot	df.para + df.smooth
list.smf	List of all smf.smooth.spec objects contained in the model
list.tensor	List of all tensor.smooth.spec objects contained in the model
list.tint	List of all tint. smooth. spec objects contained in the model
nb.smooth	number of smoothing parameters
Z.smf	List of matrices that represents the sum-to-zero constraints to apply for $\ensuremath{smf}$ splines
Z.tensor	List of matrices that represents the sum-to-zero constraints to apply for tensor splines
Z.tint	List of matrices that represents the sum-to-zero constraints to apply for tint splines
beta.ini	initial set of regression parameters

### **Examples**

```
library(survPen)
# standard spline of time with 4 knots

data <- data.frame(time=seq(0,5,length=100),event=1,t0=0)

form <- ~ smf(time,knots=c(0,1,3,5))

t1 <- eval(substitute(time), data)
t0 <- eval(substitute(t0), data)
event <- eval(substitute(event), data)

# The following code sets up everything we need in order to fit the model
model.c <- model.cons(form,lambda=0,data.spec=data,t1=t1,t1.name="time",
t0=rep(0,100),t0.name="t0",event=event.event.name="event",
expected=rep(0,100),expected.name=NULL,type="overall",n.legendre=20,
cl="survPen(form,data,t1=time,event=event)",beta.ini=NULL)</pre>
```

NR.beta Inner Newton-Raphson algorithm for regression parameters estimation

# Description

Applies Newton-Raphson algorithm for beta estimation. Two specific modifications aims at guaranteeing convergence: first the hessian is perturbed whenever it is not positive definite and second, at each step, if the penalized log-likelihood is not maximized, the step is halved until it is.

26 NR.beta

### Usage

```
NR.beta(build, beta.ini, detail.beta, max.it.beta = 200, tol.beta = 1e-04)
```

### **Arguments**

build	list of objects returned by model.cons
beta.ini	vector of initial regression parameters; default is NULL, in which case the first beta will be log(sum(event)/sum(t1)) and the others will be zero (except if there are "by" variables or if there is a piecewise constant hazard specification in which cases all betas are set to zero)
detail.beta	if TRUE, details concerning the optimization process in the regression parameters are displayed; default is FALSE
max.it.beta	maximum number of iterations to reach convergence in the regression parameters; default is $200$
tol.beta	convergence tolerance for regression parameters; default is 1e-04

### **Details**

If we note 11.pen and beta respectively the current penalized log-likelihood and estimated parameters and 11.pen.old and betaold the previous ones, the algorithm goes on while (abs(ll.pen-ll.pen.old)>tol.beta) or any(abs((beta-betaold)/betaold)>tol.beta)

### Value

List of objects:

beta estimated regression parameters

11.unpen log-likelihood at convergence

11.pen penalized log-likelihood at convergenceiter.beta number of iterations needed to converge

# Examples

```
library(survPen)

# standard spline of time with 4 knots

data <- data.frame(time=seq(0,5,length=100),event=1,t0=0)

form <- ~ smf(time,knots=c(0,1,3,5))

t1 <- eval(substitute(time), data)
t0 <- eval(substitute(t0), data)
event <- eval(substitute(event), data)

# Setting up the model before fitting
model.c <- model.cons(form,lambda=0,data.spec=data,t1=t1,t1.name="time",
t0=rep(0,100),t0.name="t0",event=event,event.name="event",</pre>
```

NR.rho 27

```
expected=rep(0,100), expected.name=NULL, type="overall", n.legendre=20,
cl="survPen(form,data,t1=time,event=event)",beta.ini=NULL)
# Estimating the regression parameters at given smoothing parameter (here lambda=0)
Newton1 <- NR.beta(model.c,beta.ini=rep(0,4),detail.beta=TRUE)</pre>
```

NR.rho

Outer Newton-Raphson algorithm for smoothing parameters estimation via LCV or LAML optimization

### Description

Applies Newton-Raphson algorithm for smoothing parameters estimation. Two specific modifications aims at guaranteeing convergence: first the hessian is perturbed whenever it is not positive definite and second, at each step, if LCV or -LAML is not minimized, the step is halved until it is.

### Usage

```
NR.rho(
 build,
  rho.ini,
  data,
  formula,
 max.it.beta = 200,
 max.it.rho = 30,
  beta.ini = NULL,
  detail.rho = FALSE,
  detail.beta = FALSE,
  nb.smooth,
  tol.beta = 1e-04,
  tol.rho = 1e-04,
  step.max = 5,
  method = "LAML"
)
```

#### **Arguments**

build	list of objects returned by model.cons
rho.ini	vector of initial log smoothing parameters; if it is NULL, all log lambda are set to -1 $$
data	an optional data frame containing the variables in the model
formula	formula object specifying the model
max.it.beta	maximum number of iterations to reach convergence in the regression parame-

ters; default is 200

28 NR.rho

max.it.rho	maximum number of iterations to reach convergence in the smoothing parameters; default is 30
beta.ini	vector of initial regression parameters; default is NULL, in which case the first beta will be log(sum(event)/sum(t1)) and the others will be zero (except if there are "by" variables or if there is a piecewise constant hazard specification in which cases all betas are set to zero)
detail.rho	if TRUE, details concerning the optimization process in the smoothing parameters are displayed; default is FALSE
detail.beta	if TRUE, details concerning the optimization process in the regression parameters are displayed; default is FALSE
nb.smooth	number of smoothing parameters
tol.beta	convergence tolerance for regression parameters; default is 1e-04
tol.rho	convergence tolerance for smoothing parameters; default is 1e-04
step.max	maximum absolute value possible for any component of the step vector (on the log smoothing parameter scale); default is 5
method	LCV or LAML; default is LAML

### **Details**

If we note val the current LCV or LAML value, val.old the previous one and grad the gradient vector of LCV or LAML with respect to the log smoothing parameters, the algorithm goes on while(abs(val-val.old)>tol.rho|any(abs(grad)>tol.rho))

#### Value

object of class survPen (see survPen.fit for details)

# Examples

```
library(survPen)

# standard spline of time with 4 knots

data <- data.frame(time=seq(0,5,length=100),event=1,t0=0)

form <- ~ smf(time,knots=c(0,1,3,5))

t1 <- eval(substitute(time), data)
 t0 <- eval(substitute(t0), data)
 event <- eval(substitute(event), data)

# Setting up the model before fitting
model.c <- model.cons(form,lambda=0,data.spec=data,t1=t1,t1.name="time",
t0=rep(0,100),t0.name="t0",event=event,event.name="event",
expected=0,expected.name=NULL,type="overall",n.legendre=20,
cl="survPen(form,data,t1=time,event=event)",beta.ini=NULL)

# Estimating the smoothing parameter and the regression parameters</pre>
```

predict.survPen 29

```
# we need to apply a reparameterization to model.c before fitting
constructor <- repam(model.c)$build # model constructor
constructor$optim.rho <- 1 # we tell it we want to estimate the log smoothing parameters (rho)
Newton2 <- NR.rho(constructor,rho.ini=-1,data,form,nb.smooth=1,detail.rho=TRUE)</pre>
```

predict.survPen

Hazard and Survival prediction from fitted survPen model

### **Description**

Takes a fitted survPen object and produces hazard and survival predictions given a new set of values for the model covariates.

### Usage

```
## S3 method for class 'survPen'
predict(
   object,
   newdata,
   newdata.ref = NULL,
   n.legendre = 50,
   conf.int = 0.95,
   do.surv = TRUE,
   type = "standard",
   exclude.random = FALSE,
   get.deriv.H = FALSE,
   ...
)
```

# Arguments

object	a fitted survPen object as produced by survPen.fit
newdata	data frame giving the new covariates value
newdata.ref	data frame giving the new covariates value for the reference population (used only when type="HR")
n.legendre	number of nodes to approximate the cumulative hazard by Gauss-Legendre quadrature; default is $50$
conf.int	numeric value giving the precision of the confidence intervals; default is 0.95
do.surv	If TRUE (the default), the survival (or cumulative ratio for type='mult') and its lower and upper confidence values are computed. Survival computation requires numerical integration and can be time-consuming so if you only want the hazard use do.surv=FALSE; default is TRUE
type	if type="lpmatrix" returns the design matrix (or linear predictor matrix) corresponding to the new values of the covariates; if equals "HR", returns the predicted HR and survival difference (with CIs) between newdata and newdata.ref; default is "standard" for classical hazard and survival estimation

30 predict.survPen

exclude.random if TRUE all random effects are set to zero; default is FALSE

get.deriv.H if TRUE, the derivatives wrt to the regression parameters of the cumulative hazard are returned; default is FALSE

other arguments

### **Details**

The confidence intervals noted CI.U are built on the log cumulative hazard scale U=log(H) (efficient scale in terms of respect towards the normality assumption) using Delta method. The confidence intervals on the survival scale are then CI.surv = exp(-exp(CI.U))

### Value

List of objects:

haz	hazard predicted by the model
haz.inf	lower value for the confidence interval of the hazard based on the Bayesian covariance matrix Vp (Wood et al. 2016)
haz.sup	Upper value for the confidence interval of the hazard based on the Bayesian covariance matrix Vp
surv	survival predicted by the model
surv.inf	lower value for the confidence interval of the survival based on the Bayesian covariance matrix Vp
surv.sup	Upper value for the confidence interval of the survival based on the Bayesian covariance matrix Vp
deriv.H	derivatives wrt to the regression parameters of the cumulative hazard. Useful to calculate standardized survival
HR	predicted hazard ratio; only when type = "HR"
HR.inf	lower value for the confidence interval of the hazard ratio based on the Bayesian covariance matrix Vp; only when type = "HR"
HR.sup	Upper value for the confidence interval of the hazard ratio based on the Bayesian covariance matrix Vp; only when type = "HR"
surv.diff	predicted relative difference; only when type = "HR"
surv.diff.inf	lower value for the confidence interval of the survival difference based on the Bayesian covariance matrix $Vp$ ; only when $type = "HR"$
surv.diff.sup	Upper value for the confidence interval of the survival difference based on the Bayesian covariance matrix Vp; only when type = "HR"
ratio	relative mortality ratio predicted by the model ; only for relative mortality ratio model (type="mult")
ratio.inf	lower value for the confidence interval of the relative mortality ratio based on the Bayesian covariance matrix Vp (Wood et al. 2016); only for relative mortality ratio model (type="mult")
ratio.sup	Upper value for the confidence interval of the relative mortality ratio on the Bayesian covariance matrix Vp; only for relative mortality ratio model (type="mult")

predict.survPen 31

cumul.ratio cumulative relative mortality ratio predicted by the model; only for relative mortality ratio model (type="mult") cumul.ratio.inf lower value for the confidence interval of the cumulative relative mortality ratio based on the Bayesian covariance matrix Vp (Wood et al. 2016); only for relative mortality ratio model (type="mult") cumul.ratio.sup Upper value for the confidence interval of the cumulative relative mortality ratio on the Bayesian covariance matrix Vp; only for relative mortality ratio model (type="mult") RR predicted ratio of relative mortality ratios; only for relative mortality ratio model when type = "HR" RR.inf lower value for the confidence interval of the ratio of relative mortality ratios based on the Bayesian covariance matrix Vp; only for relative mortality ratio model when type = "HR" Upper value for the confidence interval of the ratio of relative mortality ratios RR. sup based on the Bayesian covariance matrix Vp; only for relative mortality ratio model when type = "HR"

### **Examples**

```
library(survPen)
data(datCancer) # simulated dataset with 2000 individuals diagnosed with cervical cancer
f1 <- ~tensor(fu,age,df=c(5,5))
# hazard model
mod1 <- survPen(f1,data=datCancer,t1=fu,event=dead,expected=NULL,method="LAML")</pre>
# predicting hazard and survival curves for age 60
nt <- seq(0,5,1e=50)
pred <- predict(mod1,data.frame(fu=nt,age=60))</pre>
pred$haz
pred$surv
# predicting hazard ratio at 1 year according to age (with reference age of 50)
newdata1 <- data.frame(fu=1,age=seq(30,90,by=1))</pre>
newdata.ref1 <- data.frame(fu=1,age=rep(50,times=61))</pre>
predHR_1 <- predict(mod1,newdata=newdata1,newdata.ref=newdata.ref1,type="HR")</pre>
predHR_1$HR
predHR_1$HR.inf
predHR_1$HR.sup
# predicting hazard ratio at 3 years according to age (with reference age of 50)
# and difference of survival at 3 years
```

32 predSNS

```
newdata3 <- data.frame(fu=3,age=seq(30,90,by=1))
newdata.ref3 <- data.frame(fu=3,age=rep(50,times=61))
predHR_3 <- predict(mod1,newdata=newdata3,newdata.ref=newdata.ref3,type="HR")
# Hazard ratio
predHR_3$HR
predHR_3$HR.inf
predHR_3$HR.sup
# Difference of survival
predHR_3$diff.surv
predHR_3$diff.surv.inf
predHR_3$diff.surv.sup</pre>
```

predSNS

Prediction of grouped indicators: population (net) survival (PNS) and age-standardized (net) survival (SNS)

# Description

Allows the prediction of population and age-standardized (net) survival as well as associated confidence intervals

# Usage

```
predSNS(
  model,
  time.points,
  newdata,
  weight.table,
  var.name,
  var.model,
  conf.int = 0.95,
  method = "exact",
  n.legendre = 50
)
```

### **Arguments**

model a fitted survPen model time.points vector of follow-up values

newdata dataset containing the original age values used for fitting

weight.table dataset containing the age classes used for standardization, must be in the same

format as the elements of the following list list.wicss

predSNS 33

var.name	list containing one element: the column name in newdata that reports age values. This element should be named after the age variable present in the model formula. Typically, if newdata contains an 'age' column while the model uses a centered age 'agec', the list should be: list(agec="age")
var.model	list containing one element: the function that allows retrieving the age variable used in model formula from original age. Typically for age centered on 50, list(agec=function(age) age - 50)
conf.int	numeric value giving the precision of the confidence intervals; default is 0.95
method	should be either 'exact' or 'approx'. The 'exact' method uses all age values in newdata for predictions. The 'approx' method uses either newdata\$age (if age values are whole numbers) or floor(newdata\$age) + 0.5 (if age values are not whole numbers) and then removes duplicates to reduce computational cost.
n.legendre	number of nodes to approximate the cumulative hazard by Gauss-Legendre quadrature: default is 50

# **Details**

The weight table used should always be in the same format as elements of list.wicss. Only age-standardization is possible for now. All other variables necessary for model predictions should be fixed to a single value. For simplicity, in what follows we will consider that survival only depends on time and age.

# Value

### List of nine elements

class.table	Number of individuals in each age class
SNS	Vector of predicted age-standardized (net) survival
SNS.inf	Lower bound of confidence intervals associated with predicted age-standardized (net) survival
SNS.sup	Upper bound of confidence intervals associated with predicted age-standardized (net) survival
PNS	Vector of predicted population (net) survival
PNS.inf	Lower bound of confidence intervals associated with predicted population (net) survival
PNS.sup	Upper bound of confidence intervals associated with predicted population (net) survival
PNS_per_class	matrix of predicted population (net) survival in each age class
PNS_per_class.inf	
	Lower bound of confidence intervals associated with predicted population (net) survival in each age class
PNS_per_class.sup	
	Upper bound of confidence intervals associated with predicted population (net)

survival in each age class

34 predSNS

### **Population Net Survival (PNS)**

For a given group of individuals, PNS at time t is defined as

$$PNS(t) = \sum_{i} 1/n * S_i(t, a_i)$$

where  $a_i$  is the age of individual i

#### Standardized Net Survival (SNS)

SNS at time t is defined as

$$SNS(t) = \sum_{i} w_i * S_i(t, a_i)$$

where  $a_i$  is the age of individual i and  $w_i = w_{refj(i)}/n_{j(i)}$ .  $w_{refj(i)}$  is the weight of age class j in the reference population (it corresponds to weight.table\$AgeWeights). Where  $n_{j(i)}$  is the total number of individuals present in age class j(i): the age class of individual i.

#### Standardized Net Survival (SNS) with method="approx"

For large datasets, SNS calculation is quite heavy. To reduce computational cost, the idea is to regroup individuals who have similar age values. By using floor(age) + 0.5 instead of age, the gain will be substantial while the prediction error will be minimal (method="approx" will give slightly different predictions compared to method="exact"). Of course, if the provided age values are whole numbers then said provided age values will be used directly for grouping and there will be no prediction error (method="approx" and method="exact" will give the exact same predictions).

$$SNS(t) = \sum_{a} \tilde{w}_a * S(t, a)$$

The sum is here calculated over all possible values of age instead of all individuals. We have  $\tilde{w}_a = n_a * w_{refj(a)}/n_{j(a)}$ . Where j(a) is the age class of age a while  $n_a$  is the number of individuals with age a.

### Variance and Confidence Intervals

Confidence intervals for SNS are derived assuming normality of log(log(-SNS)) Lower and upper bound are given by

$$IC_{95\%}(SNS) = [SNS^{1.96*\sqrt{(Var(Log(Delta_{SNS})))}}; SNS^{-1.96*\sqrt{(Var(Log(Delta_{SNS})))}}]$$

with

$$Delta_{SNS} = -log(SNS)$$

 $Var(Log(Delta_{SNS}))$  is derived by Delta method.

Confidence intervals for PNS are derived in the exact same way.

x an object of class summary.survPen
 digits controls number of digits printed in output.
 signif.stars Should significance stars be printed alongside output.
 other arguments

#### Value

print of summary

pwcst

Defining piecewise constant (excess) hazard in survPen formulae

### **Description**

Used inside a formula object to define a piecewise constant (excess) hazard. This is useful since it triggers an explicit calculation of cumulative hazard calculation (much more efficient and more precise than Gauss-Legendre quadrature when hazard is constant). The breaks given are used to defined sub-intervals that are left-open (except the first interval which is always left-closed) and right-closed. Internally, this constructor uses the cut function on the follow-up time with options include.lowest=TRUE and right=TRUE Important: this function must not be used with other time-dependent effect functions because the Gauss-Legendre quadrature will not operate correctly. If you really want to fit such a model, please use the cut function with the time variable as an argument to fit a piecewise constant hazard (and do not forget to use a huge number of Gauss-Legendre quadrature nodes, typically n.legendre=500)

### Usage

```
pwcst(breaks)
```

#### **Arguments**

breaks

numeric vector that specifies the boundaries of each sub-interval on which the hazard is constant

### Value

```
object of class pwcst.spec
```

pwcst.breaks

numeric vector that specifies the boundaries of each sub-interval on which the hazard is constant

rd 37

# **Examples**

```
library(survPen)
data(datCancer)

# piece constant hazard on 6 sub-intervals : [0;0.5]; ]0.5;1]; ]1;2]; ]2;3]; ]3;4]; ]4;5]
formula <- ~pwcst(breaks=c(0,0.5,1,2,3,4,5))
mod <- survPen(formula,t1=fu,event=dead,data=datCancer)

# The same but in an inefficient way
formula2 <- ~cut(fu,breaks=c(0,0.5,1,2,3,4,5),include.lowest=TRUE,right=TRUE)
mod.inefficient <- survPen(formula2,t1=fu,event=dead,data=datCancer,n.legendre=500)</pre>
```

rd

Defining random effects in survPen formulae

# **Description**

Used inside a formula object to define a random effect.

## Usage

```
rd(...)
```

# Arguments

... Any number of covariates separated by ","

#### Value

```
object of class rd. smooth. spec
```

```
# cubic regression spline of time with 10 unspecified knots + random effect at the cluster level
formula.test <- ~smf(time,df=10) + rd(cluster)</pre>
```

38 repam

repam Applies initial reparameterization for stable evaluation of the log determinant of the penalty matrix

## **Description**

Transforms the object from model.cons by applying the matrix reparameterization (matrix U.F). The reparameterization is reversed at convergence by inv. repam.

## Usage

```
repam(build)
```

# **Arguments**

build object as returned by model.cons

## Value

build an object as returned by model.cons

X. ini initial design matrix (before reparameterization)

S.pen.ini initial penalty matrices

```
library(survPen)

# standard spline of time with 4 knots

data <- data.frame(time=seq(0,5,length=100),event=1,t0=0)

form <- ~ smf(time,knots=c(0,1,3,5))

t1 <- eval(substitute(time), data)
 t0 <- eval(substitute(t0), data)
 event <- eval(substitute(event), data)

# Setting up the model before fitting
model.c <- model.cons(form,lambda=0,data.spec=data,t1=t1,t1.name="time",
t0=rep(0,100),t0.name="t0",event=event,event.name="event",
expected=rep(0,100),expected.name=NULL,type="overall",n.legendre=20,
cl="survPen(form,data,t1=time,event=event)",beta.ini=NULL)

# Reparameterization allows separating the parameters into unpenalized and
# penalized ones for maximum numerical stability
re.model.c <- repam(model.c)</pre>
```

robust.var 39

robust.var

Implementation of the robust variance Vr

# **Description**

Takes the model at convergence and calculates the robust variance matrix accounting for correlated survival times

#### Usage

```
robust.var(model, data, cluster.name, n.legendre = 50)
```

# **Arguments**

model survPen object, see survPen.fit for details

data original dataset

cluster.name name of cluster variable in data

n.legendre number of nodes for Gauss-Legendre quadrature; default is 50

#### Value

survPen object with robust variance Vr

smf

Defining smooths in survPen formulae

## **Description**

Used inside a formula object to define a smooth, a tensor product smooth or a tensor product interaction. Natural cubic regression splines (linear beyond the knots, equivalent to ns from package splines) are used as marginal bases. While tensor builds a tensor product of marginal bases including the intercepts, tint applies a tensor product of the marginal bases without their intercepts. Unlike tensor, the marginal effects of the covariates should also be present in the formula when using tint. For a conceptual difference between tensor products and tensor product interactions see Section 5.6.3 from Wood (2017)

# Usage

```
smf(..., knots = NULL, df = NULL, by = NULL, same.rho = FALSE)
tensor(..., knots = NULL, df = NULL, by = NULL, same.rho = FALSE)
tint(..., knots = NULL, df = NULL, by = NULL, same.rho = FALSE)
```

40 smf

#### **Arguments**

Any number of covariates separated by ","
 knots
 numeric vector that specifies the knots of the splines (including boundaries); default is NULL, in which case the knots are spread through the covariate values using quantiles. Precisely, for the term "smf(x,df=df1)", the vector of knots will be: quantile(unique(x),seq(0,1,length=df1))
 df
 numeric value that indicates the number of knots (or degrees of freedom) desired; default is NULL. If knots and df are NULL, df will be set to 10
 by
 numeric or factor variable in order to define a varying coefficient smooth
 same.rho
 if the specified by variable is a factor, specifies whether the smoothing parameters should be the same for all levels; default is FALSE.

#### Value

object of class smf.smooth.spec, tensor.smooth.spec or tint.smooth.spec (see smooth.spec for details)

#### References

Wood, S. N. (2017), Generalized additive models: an introduction with R. Second Edition. London: Chapman & Hall/CRC.

```
# penalized cubic regression spline of time with 5 unspecified knots
formula.test <- ~smf(time,df=5)</pre>
# suppose that we want to fit a model from formula.test

```

smooth.cons

Design and penalty matrices of penalized splines in a smooth.spec object

## **Description**

Builds the design and penalty matrices from the result of smooth.spec.

## Usage

```
smooth.cons(
  term,
  knots,
  df,
  by = NULL,
  option,
  data.spec,
  same.rho = FALSE,
  name
)
```

term	Vector of strings that generally comes from the value "term" of a smooth.spec object.
knots	List of numeric vectors that specifies the knots of the splines (including boundaries).
df	Degrees of freedom: numeric vector that indicates the number of knots desired for each covariate.
by	numeric or factor variable in order to define a varying coefficient smooth; default is NULL.
option	"smf", "tensor" or "tint".
data.spec	data frame that represents the environment from which the covariate values and knots are to be calculated; default is NULL.
same.rho	if there is a factor by variable, should the smoothing parameters be the same for all levels; default is FALSE.
name	simplified name of the smooth.spec call.

42 smooth.cons.integral

# Value

List of objects with the following items:

X	Design matrix
pen	List of penalty matrices
term	Vector of strings giving the names of each covariate
knots	list of numeric vectors that specifies the knots for each covariate
dim	Number of covariates
all.df	Numeric vector giving the number of knots associated with each covariate
sum.df	Sum of all.df
Z.smf	List of matrices that represents the sum-to-zero constraint to apply for "smf" splines
Z.tensor	List of matrices that represents the sum-to-zero constraint to apply for "tensor" splines
Z.tint	List of matrices that represents the sum-to-zero constraint to apply for "tint" splines
lambda.name	name of the smoothing parameters

# **Examples**

```
library(survPen)
# standard spline of time with 4 knots (so we get a design matrix with 3 columns
# because of centering constraint)

data <- data.frame(time=seq(0,5,length=100))
smooth.c <- smooth.cons("time",knots=list(c(0,1,3,5)),df=4,option="smf",
data.spec=data,name="smf(time)")</pre>
```

 ${\it smooth.cons.integral} \quad {\it Design \ matrix \ of \ penalized \ splines \ in \ a \ smooth.spec \ object \ for \ Gauss-Legendre \ quadrature}$ 

# Description

Almost identical to smooth.cons. This version is dedicated to Gauss-Legendre quadrature. Here, the sum-to-zero constraints must be specified so that they correspond to the ones that were calculated with the initial dataset.

smooth.cons.integral 43

# Usage

```
smooth.cons.integral(
   term,
   knots,
   df,
   by = NULL,
   option,
   data.spec,
   Z.smf,
   Z.tensor,
   Z.tint,
   name
)
```

# Arguments

term	Vector of strings that generally comes from the value "term" of a smooth.spec object
knots	List of numeric vectors that specifies the knots of the splines (including boundaries).
df	Degrees of freedom: numeric vector that indicates the number of knots desired for each covariate.
by	numeric or factor variable in order to define a varying coefficient smooth; default is NULL.
option	"smf", "tensor" or "tint".
data.spec	data frame that represents the environment from which the covariate values and knots are to be calculated; default is NULL.
Z.smf	List of matrices that represents the sum-to-zero constraint to apply for $\ensuremath{smf}$ splines.
Z.tensor	List of matrices that represents the sum-to-zero constraint to apply for tensor splines.
Z.tint	List of matrices that represents the sum-to-zero constraint to apply for tint splines.
name	simplified name of the smooth.spec call.

# Value

design matrix

```
library(survPen)
# standard spline of time with 4 knots (so we get a design matrix with 3 columns
# because of centering constraint)
```

smooth.spec

```
data <- data.frame(time=seq(0,5,length=100))

# retrieving sum-to-zero constraint matrices
Z.smf <- smooth.cons("time",knots=list(c(0,1,3,5)),df=4,option="smf",
data.spec=data,name="smf(time)")$Z.smf

# constructing the design matrices for Gauss-Legendre quadrature
smooth.c.int <- smooth.cons.integral("time",knots=list(c(0,1,3,5)),df=4,option="smf",data.spec=data,name="smf(time)",Z.smf=Z.smf,Z.tensor=NULL,Z.tint=NULL)</pre>
```

smooth.spec

Covariates specified as penalized splines

# Description

Specifies the covariates to be considered as penalized splines.

# Usage

```
smooth.spec(
    ...,
    knots = NULL,
    df = NULL,
    by = NULL,
    option = NULL,
    same.rho = FALSE
)
```

• • •	Numeric vectors specified in smf, tensor or tint
knots	List of numeric vectors that specifies the knots of the splines (including boundaries); default is NULL
df	Degrees of freedom: numeric vector that indicates the number of knots desired for each covariate; default is NULL
by	numeric or factor variable in order to define a varying coefficient smooth; default is NULL
option	"smf", "tensor" or "tint". Depends on the wrapper function; default is "smf"
same.rho	if there is a factor by variable, should the smoothing parameters be the same for all levels; default is FALSE.

splitmult 45

## Value

object of class smooth.spec

term Vector of strings giving the names of each covariate specified in ...

dim Numeric value giving the number of covariates associated with this spline

knots list of numeric vectors that specifies the knots for each covariate

df Numeric vector giving the number of knots associated with each covariate by numeric or factor variable in order to define a varying coefficient smooth

same.rho if there is a factor by variable, should the smoothing parameters be the same for

all levels; default is FALSE

name simplified name of the call to function smooth.spec

## **Examples**

```
library(survPen)

# standard spline of time with 10 unspecified knots
smooth.spec(time)

# tensor of time and age with 5*5 specified knots
smooth.s <- smooth.spec(time,age,knots=list(time=seq(0,5,length=5),age=seq(20,80,length=5)),
option="tensor")</pre>
```

splitmult

Split original dataset at specified times to fit a multiplicative model

# **Description**

This function allows splitting the original dataset in order to retrieve all the expected mortality rates available according to each individual's follow-up time. Typically, the expected mortality rates come from national mortality tables and values are available for every combination of age and year (often with 1-year increment).

## Usage

```
splitmult(data, cut, start = NULL, end, event)
```

data	orginal datset	
cut	vector of timepoints to cut at (usually every year of follow-up)	
start	character string with name of start variable (will be created and set to ze does not exist)	ro if it
end	character string with name of event time variable	
event	character string with name of censoring indicator	

46 summary.survPen

## **Details**

This function is close to the survsplit function proposed in relsurv package, but it is simpler since fewer features are needed.

#### Value

split dataset with follow-up time split at specified times. An 'id\_row' column is added to identify original row numbers

# Examples

summary.survPen

Summary for a survPen fit

## **Description**

Takes a fitted survPen object and produces various useful summaries from it.

## Usage

```
## S3 method for class 'survPen'
summary(object, ...)
```

```
object a fitted survPen object as produced by survPen.fit
... other arguments
```

summary.survPen 47

#### Value

List of objects:

call the original survPen call formula the original survPen formula

coefficients reports the regression parameters estimates for unpenalized terms with the asso-

ciated standard errors

HR\_TAB reports the exponential of the regression parameters estimates for unpenalized

terms with the associated CI

edf.per.smooth reports the edf associated with each smooth term random TRUE if there are random effects in the model

random.effects reports the estimates of the log standard deviation (log(sd)) of every random

effects plus the estimated standard error (also on the log(sd) scale)

likelihood unpenalized likelihood of the model

penalized.likelihood

penalized likelihood of the model

nb. smooth number of smoothing parameters

smoothing.parameter

smoothing parameters estimates

parameters number of regression parameters edf effective degrees of freedom

method smoothing selection criterion used (LAML or LCV)

val.criterion minimized value of criterion. For LAML, what is reported is the negative log

marginal likelihood

converged convergence indicator, TRUE or FALSE. TRUE if Hess.beta.modif=FALSE and

Hess.rho.modif=FALSE (or NULL)

# **Examples**

summary(mod1)

```
library(survPen)

data(datCancer) # simulated dataset with 2000 individuals diagnosed with cervical cancer

# model : unidimensional penalized spline for time since diagnosis with 5 knots
f1 <- ~smf(fu,df=5)

# fitting hazard model
mod1 <- survPen(f1,data=datCancer,t1=fu,event=dead,expected=NULL,method="LAML")
# summary</pre>
```

survPen

(Excess) hazard model with (multidimensional) penalized splines and integrated smoothness estimation

## Description

Please have a look to survival\_analysis\_with\_survPen vignette for a thorough description.

Fits an (excess) hazard model with (multidimensional) penalized splines allowing for time-dependent effects, non-linear effects and interactions between several continuous covariates. The linear predictor is specified on the logarithm of the (excess) hazard. Smooth terms are represented using cubic regression splines with associated quadratic penalties. For multidimensional smooths, tensor product splines or tensor product interactions are available. Smoothness is estimated automatically by optimizing one of two criteria: Laplace approximate marginal likelihood (LAML) or likelihood cross-validation (LCV). When specifying the model's formula, no distinction is made between the part relative to the form of the baseline hazard and the one relative to the effects of the covariates. Thus, time-dependent effects are naturally specified as interactions with some function of time via "\*" or ":". See the examples below for more details. The main functions of the survPen package are survPen, smf, tensor, tint and rd. The first one fits the model while the other four are constructors for penalized splines.

The user must be aware that the survPen package does not depend on mgcv. Thus, all the functionalities available in mgcv in terms of types of splines (such as thin plate regression splines or P-splines) are not available in survPen (yet).

#### Usage

```
survPen(
  formula,
  data,
  t1,
  t0 = NULL
  event,
 expected = NULL,
  lambda = NULL,
  rho.ini = NULL,
 max.it.beta = 200,
 max.it.rho = 30,
 beta.ini = NULL,
  detail.rho = FALSE,
  detail.beta = FALSE,
  n.legendre = NULL,
 method = "LAML",
  tol.beta = 1e-04,
  tol.rho = 1e-04,
  step.max = 5,
  type = "overall",
```

```
cluster = NULL
)
```

formula	formula object specifying the model. Penalized terms are specified using smf (comparable to s(,bs="cr") in mgcv), tensor (comparable to te(,bs="cr") in mgcv), tint (comparable to ti(,bs="cr") in mgcv), or rd (comparable to s(,bs="re") in mgcv).
data	an optional data frame containing the variables in the model
t1	vector of follow-up times or name of the column in data containing follow-up times
t0	vector of origin times or name of the column in data containing origin times; allows to take into account left truncation; default is NULL, in which case it will be a vector of zeroes
event	vector of right-censoring indicators or name of the column in data containing right-censoring indicators; 1 if the event occurred and 0 otherwise
expected	(for net survival only) vector of expected hazard or name of the column in data containing expected hazard; default is NULL, in which case overall survival will be estimated
lambda	vector of smoothing parameters; default is NULL when it is to be estimated by LAML or LCV
rho.ini	vector of initial log smoothing parameters; default is NULL, in which case every initial log lambda will be -1
max.it.beta	maximum number of iterations to reach convergence in the regression parameters; default is 200
max.it.rho	maximum number of iterations to reach convergence in the smoothing parameters; default is 30
beta.ini	vector of initial regression parameters; default is NULL, in which case the first beta will be log(sum(event)/sum(t1)) and the others will be zero (except if there are "by" variables or if there is a piecewise constant hazard specification in which cases all betas are set to zero)
detail.rho	if TRUE, details concerning the optimization process in the smoothing parameters are displayed; default is FALSE
detail.beta	if TRUE, details concerning the optimization process in the regression parameters are displayed; default is FALSE
n.legendre	number of Gauss-Legendre quadrature nodes to be used to compute the cumulative hazard; default is NULL. If not supplied the value is set to 20 for (excess) hazard models and 10 for relative mortality ratio models
method	criterion used to select the smoothing parameters. Should be "LAML" or "LCV"; default is "LAML" $$
tol.beta	convergence tolerance for regression parameters; default is 1e-04. See NR.beta for details

tol.rho	convergence tolerance for smoothing parameters; default is 1e-04. See NR.rho for details
step.max	maximum absolute value possible for any component of the step vector (on the log smoothing parameter scale) in LCV or LAML optimization; default is 5. If necessary, consider lowering this value to achieve convergence
type	should be either 'overall' for hazard regression, 'net' for excess hazard regression, or 'mult' for relative mortality ratio regression
cluster	cluster variable for marginal hazard (intensity) models

#### **Details**

In time-to-event analysis, we may deal with one or several continuous covariates whose functional forms, time-dependent effects and interaction structure are challenging. One possible way to deal with these effects and interactions is to use the classical approximation of the survival likelihood by a Poisson likelihood. Thus, by artificially splitting the data, the package mgcv can then be used to fit penalized hazard models (Remontet et al. 2018). The problem with this option is that the setup is rather complex and the method can fail with huge datasets (before splitting). Wood et al. (2016) provided a general penalized framework that made available smooth function estimation to a wide variety of models. They proposed to estimate smoothing parameters by maximizing a Laplace approximate marginal likelihood (LAML) criterion and demonstrate how statistical consistency is maintained by doing so. The survPen function implements the framework described by Wood et al. (2016) for modelling time-to-event data without requiring data splitting and Poisson likelihood approximation. The effects of continuous covariates are represented using low rank spline bases with associated quadratic penalties. The survPen function allows to account simultaneously for time-dependent effects, non-linear effects and interactions between several continuous covariates without the need to build a possibly demanding model-selection procedure. Besides LAML, a likelihood cross-validation (LCV) criterion (O Sullivan 1988) can be used for smoothing parameter estimation. First and second derivatives of LCV with respect to the smoothing parameters are implemented so that LCV optimization is computationally equivalent to the LAML optimization proposed by Wood et al. (2016). In practice, LAML optimization is generally both a bit faster and a bit more stable so it is used as default. For m covariates  $(x_1,\ldots,x_m)$ , if we note  $h(t,x_1,\ldots,x_m)$ the hazard at time t, the hazard model is the following:

$$log[h(t, x_1, \dots, x_m)] = \sum_j g_j(t, x_1, \dots, x_m)$$

where each  $g_j$  is either the marginal basis of a specific covariate or a tensor product smooth of any number of covariates. The marginal bases of the covariates are represented as natural (or restricted) cubic splines (as in function ns from library splines) with associated quadratic penalties. Full parametric (unpenalized) terms for the effects of covariates are also possible (see the examples below). Each  $g_j$  is then associated with zero, one or several smoothing parameters. The estimation procedure is based on outer Newton-Raphson iterations for the smoothing parameters and on inner Newton-Raphson iterations for the regression parameters (see Wood et al. 2016). Estimation of the regression parameters in the inner algorithm is by direct maximization of the penalized likelihood of the survival model, therefore avoiding data augmentation and Poisson likelihood approximation. The cumulative hazard included in the log-likelihood is approximated by Gauss-Legendre quadrature for numerical stability.

#### Value

Object of class "survPen" (see survPenObject for details)

#### by variables

The smf, tensor and tint terms used to specify smooths accept an argument by. This by argument allows for building varying-coefficient models i.e. for letting smooths interact with factors or parametric terms. If a by variable is numeric, then its ith element multiples the ith row of the model matrix corresponding to the smooth term concerned. If a by variable is a factor then it generates an indicator vector for each level of the factor, unless it is an ordered factor. In the non-ordered case, the model matrix for the smooth term is then replicated for each factor level, and each copy has its rows multiplied by the corresponding rows of its indicator variable. The smoothness penalties are also duplicated for each factor level. In short a different smooth is generated for each factor level. The main interest of by variables over separated models is the same rho argument (for smf, tensor and tint) which allows forcing all smooths to have the same smoothing parameter(s). Ordered by variables are handled in the same way, except that no smooth is generated for the first level of the ordered factor. This is useful if you are interested in differences from a reference level.

See the survival\_analysis\_with\_survPen vignette for more details.

#### Random effects

i.i.d random effects can be specified using penalization. Indeed, the ridge penalty is equivalent to an assumption that the regression parameters are i.i.d. normal random effects. Thus, it is easy to fit a frailty hazard model. For example, consider the model term rd(clust) which will result in a model matrix component corresponding to model.matrix(~clust-1) being added to the model matrix for the whole model. The associated regression parameters are assumed i.i.d. normal, with unknown variance (to be estimated). This assumption is equivalent to an identity penalty matrix (i.e. a ridge penalty) on the regression parameters. The unknown smoothing parameter  $\lambda$  associated with the term rd(clust) is directly linked to the unknown variance  $\sigma^2$ :  $\sigma^2 = \frac{1}{\lambda*S.scale}$ . Then, the estimated log standard deviation is:  $log(\hat{\sigma}) = -0.5*log(\hat{\lambda}) - 0.5*log(S.scale)$ . And the estimated variance of the log standard deviation is:  $Var[log(\hat{\sigma})] = 0.25*Var[log(\hat{\lambda})] = 0.25*inv.Hess.rho$ . See the survival\_analysis\_with\_survPen vignette for more details.

This approach allows implementing commonly used random effect structures. For example if g is a factor then rd(g) produces a random parameter for each level of g, the random parameters being i.i.d. normal. If g is a factor and x is numeric, then rd(g,x) produces an i.i.d. normal random slope relating the response to x for each level of g. Thus, random effects treated as penalized splines allow specifying frailty (excess) hazard models (Charvat et al. 2016). For each individual i from cluster (usually geographical unit) j, a possible model would be:

$$log[h(t_{ij}, x_{ij1}, \dots, x_{ijm})] = \sum_{k} g_k(t_{ij}, x_{ij1}, \dots, x_{ijm}) + w_j$$

where  $w_j$  follows a normal distribution with mean 0. The random effect associated with the cluster variable is specified with the model term rd(cluster). We could also specify a random effect depending on age for example with the model term rd(cluster, age).  $u_j = exp(w_j)$  is known as the shared frailty.

See the survival\_analysis\_with\_survPen vignette for more details.

# **Excess hazard model**

When studying the survival of patients who suffer from a common pathology we may be interested in the concept of excess mortality that represents the mortality due to that pathology. For example, in cancer epidemiology, individuals may die from cancer or from another cause. The problem is that the cause of death is often either unavailable or unreliable. Supposing that the mortality due to other causes may be obtained from the total mortality of the general population (called expected mortality for cancer patients), we can define the concept of excess mortality. The excess mortality is directly linked to the concept of net survival, which would be the observed survival if patients could not die from other causes. Therefore, when such competing events are present, one may choose to fit an excess hazard model instead of a classical hazard model. Flexible excess hazard models have already been proposed (for examples see Remontet et al. 2007, Charvat et al. 2016) but none of them deals with a penalized framework (in a non-fully Bayesian setting). Excess mortality can be estimated supposing that, in patients suffering from a common pathology, mortality due to others causes than the pathology can be obtained from the (all cause) mortality of the general population; the latter is referred to as the expected mortality  $h_P$ . The mortality observed in the patients  $(h_Q)$ is actually decomposed as the sum of  $h_P$  and the excess mortality due to the pathology  $(h_E)$ . This may be written as:

$$h_O(t, x) = h_E(t, x) + h_P(a + t, z)$$

In that equation, t is the time since cancer diagnosis, a is the age at diagnosis,  $h_P$  is the mortality of the general population at age a+t given demographical characteristics z ( $h_P$  is considered known and available from national statistics), and x a vector of variables that may have an effect on  $h_E$ . Including the age in the model is necessary in order to deal with the informative censoring due to other causes of death. Thus, for m covariates  $(x_1, \ldots, x_m)$ , if we note  $h_E(t, x_1, \ldots, x_m)$  the excess hazard at time t, the excess hazard model is the following:

$$log[h_E(t, x_1, \dots, x_m)] = \sum_j g_j(t, x_1, \dots, x_m)$$

## Relative mortality ratio model

Another important feature of the survPen package is that it allows fitting penalized relative mortality ratio models.

As we discussed above, the excess mortality setting considers that the mortality (all causes) observed in the patients  $(h_O)$  is actually decomposed as the sum of the expected mortality  $h_P$  and the excess mortality due to the pathology  $(h_E)$ .

This may be written as:

$$h_O(t, x) = h_E(t, x) + h_P(a + t, z)$$

One limitation of such a decomposition is that  $h_E$  is considered positive. Indeed, sometimes this assumption is not met. For example, in prostate cancer patients with low stages at diagnosis, we observe an 'undermortality' due to selection effects and better overall medical care. In that case, the excess mortality is actually neagtive and the net survival setting fails to describe the reality of those patients. Besides, the excess mortality setting considers the studied disease as an independent cause of death (conditionally on the covariates) compared to the other causes. This point of view is not usely considered in multiple sclerosis epidemiology for example, where the disease is seen as a comorbidity impacting all pre- existing causes of death. In that case, the observed hazard is decomposed as product of population hazard and a relative mortality ratio r

This may be written as:

$$h_O(t,x) = r(t,x) * h_P(a+t,z)$$

This decomposition was first proposed in a modelling framework by Andersen et al. (1985). However Andersen's model was a non-flexible semi-parametric model.

The survPen package allows modelling the relative mortality ratio r as a multidimensional function of time and covariates. For m covariates  $(x_1, \ldots, x_m)$ , if we note  $r(t, x_1, \ldots, x_m)$  the relative mortality ratio at time t, the model is as follows:

$$log[r(t,x_1,\ldots,x_m)] = \sum_j g_j(t,x_1,\ldots,x_m)$$

Where the  $g_j$  functions may be penalized unidimensional or penalized tensor product splines. All features described for the (excess) hazard setting still apply when fitting a relative mortality ratio model. One difference lies in the predictions. With a fitted relative mortality ratio model, you can only retrieve the relative mortality ratio and cumulative relative mortality ratio predictions (with CIs), as well as the ratios of realtive mortality ratio (with type='HR'). No survival prediction (let alone survival difference) will be directly available because its calculation depends on expected mortality rates.

Finally, one important difference between an excess hazard model and relative mortality ratio model is data preparation. For an excess hazard model we only need individual data with expected mortality rate at the time of death. Whereas in a relative mortality ratio model, the contribution to an individual to the likelihood requires all possible expected mortality rate values during the entire follow-up. Therefore, since the expected mortality rates come from national mortality tables usually available in 1-year intervals, we need to split the original dataset as many times as there are 1-year intervals during each individual's follow-up. The function splitmult will help you getting the splitdataset from the original one.

See the survival\_analysis\_with\_survPen vignette for more details and an example of analysis.

## Marginal hazard (intensity) models with robust standard errors

In presence of correlated time-to-event data (for example recurrent event data), robust standard errors accounting for said correlation need to be derived. The 'survPen' package allows deriving such robust standard errors based on sandwich estimators (often called Huber sandwich estimator, see also Coz et al. submitted to Biostatistics, for an example in the recurrent event setting).

The user only needs to specify the 'cluster' variable defining the statistical units for which repeated observations are available. This specification is performed via the 'cluster' argument.

See the survival\_analysis\_with\_survPen vignette for more details and an example of analysis.

## Convergence

No convergence indicator is given. If the function returns an object of class survPen, it means that the algorithm has converged. If convergence issues occur, an error message is displayed. If convergence issues occur, do not refrain to use detail.rho and/or detail.beta to see exactly what is going on in the optimization process. To achieve convergence, consider lowering step.max and/or changing rho.ini and beta.ini. If your excess hazard model fails to converge, consider fitting a hazard model and use its estimated parameters as initial values for the excess hazard model. Finally, do not refrain to change the "method" argument (LCV or LAML) if convergence issues occur.

#### Other

Be aware that all character variables are transformed to factors before fitting.

survPen.fit

(Excess) hazard model with multidimensional penalized splines for given smoothing parameters

# **Description**

Fits an (excess) hazard model. If penalized splines are present, the smoothing parameters are specified

## Usage

```
survPen.fit(
  build,
  data,
  formula,
  max.it.beta = 200,
  beta.ini = NULL,
  detail.beta = FALSE,
  method = "LAML",
  tol.beta = 1e-04
)
```

## **Arguments**

build list of objects returned by model.cons

data an optional data frame containing the variables in the model

formula object specifying the model

max.it.beta maximum number of iterations to reach convergence in the regression parame-

ters; default is 200

survPenObject 61

beta.ini	vector of initial regression parameters; default is NULL, in which case the first beta will be log(sum(event)/sum(t1)) and the others will be zero (except if there are "by" variables or if there is a piecewise constant hazard specification in which cases all betas are set to zero)
detail.beta	if TRUE, details concerning the optimization process in the regression parameters are displayed; default is FALSE
method	criterion used to select the smoothing parameters. Should be "LAML" or "LCV"; default is "LAML" $$
tol.beta	convergence tolerance for regression parameters; default is 1e-04. See NR. beta for details

#### Value

Object of class "survPen" (see survPenObject for details)

# **Examples**

```
library(survPen)
# standard spline of time with 4 knots

data <- data.frame(time=seq(0,5,length=100),event=1,t0=0)

form <- ~ smf(time,knots=c(0,1,3,5))

t1 <- eval(substitute(time), data)
t0 <- eval(substitute(t0), data)
event <- eval(substitute(event), data)

# Setting up the model before fitting
model.c <- model.cons(form,lambda=0,data.spec=data,t1=t1,t1.name="time",
t0=rep(0,100),t0.name="t0",event=event,event.name="event",
expected=rep(0,100),expected.name=NULL,type="overall",n.legendre=20,
cl="survPen(form,data,t1=time,event=event)",beta.ini=NULL)

# fitting
mod <- survPen.fit(model.c,data,form)</pre>
```

survPenObject

Fitted survPen object

# Description

A fitted survPen object returned by function survPen and of class "survPen". Method functions predict and summary are available for this class.

62 survPenObject

#### Value

A survPen object has the following elements:

call original survPen call

formula formula object specifying the model t0.name name of the vector of origin times t1.name name of the vector of follow-up times

event.name name of the vector of right-censoring indicators

expected.name name of the vector of expected hazard

haz fitted hazard

coefficients estimated regression parameters. Unpenalized parameters are first, followed by

the penalized ones

type "net" for net survival estimation with penalized excess hazard model, "overall"

for overall survival with penalized hazard model, or "mult" for penalized relative

mortality ratio model

df.para degrees of freedom associated with fully parametric terms (unpenalized)

df.smooth degrees of freedom associated with penalized terms

p number of regression parameters edf effective degrees of freedom

edf1 alternative effective degrees of freedom; used as an upper bound for edf2
edf2 effective degrees of freedom corrected for smoothing parameter uncertainty
aic Akaike information criterion with number of parameters replaced by edf when

there are penalized terms. Corresponds to 2\*edf - 2\*ll.unpen

aic2 Akaike information criterion corrected for smoothing parameter uncertainty.

Be careful though, this is still a work in progress, especially when one of the

smoothing parameters tends to infinity.

iter.beta vector of numbers of iterations needed to estimate the regression parameters for

each smoothing parameters trial. It thus contains iter.rho+1 elements.

X design matrix of the model
S penalty matrix of the model

S. scale vector of rescaling factors for the penalty matrices

S.list Equivalent to pen but with every element multiplied by its associated smoothing

parameter

S. smf List of penalty matrices associated with all "smf" calls
S. tensor List of penalty matrices associated with all "tensor" calls
S. tint List of penalty matrices associated with all "tint" calls
S. rd List of penalty matrices associated with all "rd" calls

smooth.name.smf

List of names for the "smf" calls associated with S.smf

smooth.name.tensor

List of names for the "tensor" calls associated with S.tensor

survPenObject 63

smooth.name.tint

List of names for the "tint" calls associated with S.tint

smooth.name.rd List of names for the "rd" calls associated with S.rd

S.pen List of all the rescaled penalty matrices redimensioned to df.tot size. Every

element of S.pen noted S.pen[[i]] is made from a penalty matrix pen[[i]]

returned by smooth.cons and is multiplied by S.scale

grad.unpen.beta

gradient vector of the log-likelihood with respect to the regression parameters

grad.beta gradient vector of the penalized log-likelihood with respect to the regression

parameters

Hess.unpen.beta

hessian of the log-likelihood with respect to the regression parameters

Hess. beta hessian of the penalized log-likelihood with respect to the regression parameters

Hess.beta.modif

if TRUE, the hessian of the penalized log-likelihood has been perturbed at con-

vergence

11. unpen log-likelihood at convergence

11. pen penalized log-likelihood at convergence

deriv.rho.beta transpose of the Jacobian of beta with respect to the log smoothing parameters

deriv.rho.inv.Hess.beta

list containing the derivatives of the inverse of Hess with respect to the log

smoothing parameters

deriv.rho.Hess.unpen.beta

list containing the derivatives of Hess. unpen with respect to the log smoothing

parameters

lambda estimated or given smoothing parameters

nb. smooth number of smoothing parameters

iter.rho number of iterations needed to estimate the smoothing parameters

optim.rho identify whether the smoothing parameters were estimated or not; 1 when exit-

ing the function NR. rho; default is NULL

method criterion used for smoothing parameter estimation

criterion.val value of the criterion used for smoothing parameter estimation at convergence

LCV Likelihood cross-validation criterion at convergence

LAML negative Laplace approximate marginal likelihood at convergence

grad.rho gradient vector of criterion with respect to the log smoothing parameters

Hess.rho hessian matrix of criterion with respect to the log smoothing parameters

inv.Hess.rho inverse of Hess.rho

Hess.rho.modif if TRUE, the hessian of LCV or LAML has been perturbed at convergence

Ve Frequentist covariance matrix

Vr Robust frequentist covariance matrix accounting for correlated survival times

Vp Bayesian covariance matrix

tensor.in

Vc	Bayesian covariance matrix corrected for smoothing parameter uncertainty (see Wood et al. 2016)	
Vc.approx	Kass and Steffey approximation of Vc (see Wood et al. 2016)	
Z.smf	List of matrices that represents the sum-to-zero constraint to apply for $\ensuremath{smf}$ splines	
Z.tensor	List of matrices that represents the sum-to-zero constraint to apply for tensor splines	
Z.tint	List of matrices that represents the sum-to-zero constraint to apply for tint splines	
list.smf	List of all smf.smooth.spec objects contained in the model	
list.tensor	List of all tensor.smooth.spec objects contained in the model	
list.tint	List of all tint.smooth.spec objects contained in the model	
list.rd	List of all rd. smooth. spec objects contained in the model	
U.F	Eigen vectors of S.F, useful for the initial reparameterization to separate penalized ad unpenalized subvectors. Allows stable evaluation of the log determinant of S and its derivatives	
is.pwcst	TRUE if there is a piecewise constant (excess) hazard specification. In that case the cumulative hazard can be derived without Gauss-Legendre quadrature	
pwcst.breaks	if is.pwcst is TRUE, vector of breaks defining the sub-intervals on which the hazard is constant. Otherwise NULL.	
factor.structure		
	List containing the levels and classes of all factor variables present in the data frame used for fitting	
converged	convergence indicator, TRUE or FALSE. TRUE if Hess.beta.modif=FALSE and Hess.rho.modif=FALSE (or NULL)

tensor.in	tensor model matrix for two marginal bases	

# Description

Function called recursively inside tensor.prod.X.

# Usage

tensor.in(X1, X2)

tensor.prod.S 65

# Arguments

X1	first marginal design matrix with n rows and p1 columns
X2	first marginal design matrix with n rows and p2 columns

#### Value

Matrix of dimensions n\*(p1\*p2) representing the row tensor product of the matrices X1 and X2

# **Examples**

```
library(survPen)
# row-wise tensor product between two design matrices
set.seed(15)

X1 <- matrix(rnorm(10*3),nrow=10,ncol=3)
X2 <- matrix(rnorm(10*2),nrow=10,ncol=2)
tensor.in(X1,X2)</pre>
```

tensor.prod.S

Tensor product for penalty matrices

# **Description**

Computes the penalty matrices of a tensor product smooth from the marginal penalty matrices. The code is from function tensor.prod.penalties in mgcv package.

## Usage

```
tensor.prod.S(S)
```

# **Arguments**

S list of m marginal penalty matrices

## Value

TS List of the penalty matrices associated with the tensor product smooth

```
library(survPen)
# tensor product between three penalty matrices
set.seed(15)
S1 <- matrix(rnorm(3*3),nrow=3,ncol=3)</pre>
```

66 tensor.prod.X

```
S2 <- matrix(rnorm(2*2),nrow=2,ncol=2)
S1 <- 0.5*(S1 + t(S1) ) ; S2 <- 0.5*(S2 + t(S2) )
tensor.prod.S(list(S1,S2))</pre>
```

tensor.prod.X

tensor model matrix

# **Description**

Computes the model matrix of tensor product smooth from the marginal bases.

# Usage

```
tensor.prod.X(X)
```

# **Arguments**

Χ

list of m design matrices with n rows and p1, p2, ... pm columns respectively

# Value

T

Matrix of dimensions n\*(p1\*p2\*...\*pm) representing the row tensor product of the matrices in X

```
library(survPen)
# row-wise tensor product between three design matrices
set.seed(15)

X1 <- matrix(rnorm(10*3),nrow=10,ncol=3)
X2 <- matrix(rnorm(10*2),nrow=10,ncol=2)
X3 <- matrix(rnorm(10*2),nrow=10,ncol=2)
tensor.prod.X(list(X1,X2,X3))</pre>
```

%cross% 67

%cross%

Matrix cross-multiplication between two matrices

# Description

Matrix cross-multiplication between two matrices

# Usage

```
Mat1 %cross% Mat2
```

# Arguments

Mat1 a matrix.

Mat2 another matrix.

# Value

prod the product t(Mat1)

%mult%

Matrix multiplication between two matrices

# Description

Matrix multiplication between two matrices

# Usage

```
Mat1 %mult% Mat2
```

# Arguments

Mat1 a matrix.

Mat2 another matrix.

# Value

prod the product Mat1

68 %vec%

%vec%

Matrix multiplication between a matrix and a vector

# Description

Matrix multiplication between a matrix and a vector

# Usage

Mat %vec% vec

# Arguments

Mat a matrix. vec a vector.

# Value

prod the product Mat
